Dear Sirs:

Re: Packer Leakage Test for El Paso Natural Gas
Company well: Storrey C. No. 1 (11), S. Sec.
32 - 20 - 2, N.M.

Communication between the producing zones was discovered in the Storrey C. No. (PM) on November 24, 1964. This was discovered by a temperature survey run on April 7, 1965, which showed a leak at the packer. The attachment. A workover to eliminate this communication was performed on May 18, 1965.

Initial type packer leakage tests conducted to the workover indicated a slight possibility that communication might still exist. See attachment.

A temperature survey run on September 2, 1965 did not show any communication. Another temperature survey run on December 1, 1965, installed in the vicinity, around the packer, did not indicate a leak either. See attachments.

Note the high Pictured Cliffs shut-in pressures recorded in the attached table. Also, on June 24, 1965, the Pictured Cliffs shut-in pressures were measured after being shut-in eight days. They were 4,100 and 4,590 psig casing and tubing respectively. These pressures, by dropping them toward the normal level of Pictured Cliffs pressure for that vicinity, evidence that the workover was effective in eliminating the communication.

Both zones of this well were subsequently produced to the pipeline. On December 16, 1965, seven day shut-in pressures (for a well deliverability test) were measured on the Pictured Cliffs no. 1. They were 4,100 and 4,590 psig casing and tubing respectively. These pressures, by dropping them toward the normal level of Pictured Cliffs pressure for that vicinity, evidence that the workover was effective in eliminating the communication.

It is respectfully requested that the enclosed items, including the temperature surveys and the short summary of shut-in pressures, be accepted as a satisfactory Initial Packer Leakage Test.

Very truly yours,
J. E. HARRIS
