STATE OF NEW MEXICO ENERGY, MINERALS AND NATURAL RESOURCES DEPARTMENT OIL CONSERVATION COMMISSION

APPLICATION OF NORTHWIND MIDSTREAM PARTNERS LLC FOR APPROVAL OF AN ADDITIONAL REDUNDANT ACID GAS INJECTION WELL AND TO AMEND ORDER NO. R-20913, AS AMENDED, AND SWD-2622 TO AUTHORIZE AN INCREASED SHARED MAXIMUM DAILY INJECTION RATE, LEA COUNTY, NEW MEXICO.

CASE NO. ____ ORDER NO. R-20913-D, AS AMENDED

APPLICATION

Northwind Midstream Partners LLC ("Northwind")¹ (OGRID No. 331501), through its undersigned counsel, files this application with the Oil Conservation Commission (the "Commission") pursuant to the provisions of NMSA 1978, § 70-2-12(B)(15) and 19.15.26 NMAC for an order (1) authorizing injection of treated acid gas ("TAG") for purposes of disposal into the proposed Titan AGI #4 well as an additional redundant acid gas injection ("AGI") well, and (2) to further amend Order No. R-21093-D, as amended, and SWD-2622 to authorize a shared maximum daily injection rate of 28.8 million standard cubic feet per day (MMSCFD) of treated acid gas ("TAG") for disposal through either or both its permitted Salt Creek AGI #2 well or the proposed Titan AGI #4 well. In support, Northwind states the following:

1. Attached as **Exhibit A** is a complete C-108 application for approval to drill, complete, and operate an additional redundant AGI well to service the increasing sour-gas disposal needs of Northwind's Titan Treating Facility. The C-108 also requests, and provides the technical

Released to Imaging: 9/25/2024 10:41:37 AM

¹ Effective August 18, 2023, the Division approved Northwind to be the successor operator to Salt Creek under Order No. R-20913, as amended.

basis to authorize, a shared maximum daily injection rate of 28.8 million standard cubic feet per day (MMSCFD) of treated acid gas ("TAG") for disposal into either or both its Salt Creek AGI #2 or the proposed Titan AGI #4 wells.

- 2. The proposed Titan AGI #4 will provide additional redundancy with respect to acid gas disposal operations at Northwind's Titan Treating Facility. The Facility is currently serviced by the existing Salt Creek AGI #3 well, which is a shallow Delaware Mountain Group AGI well (API No. 30-025-51865). Northwind is also currently drilling the approved Salt Creek AGI #2 well (API No. 30-025-53388), which was authorized by the Commission as a redundant AGI well to inject into the Siluro-Devonian formation.
- 3. The proposed Titan AGI #4 well will be drilled as a deviated well with a surface location of approximately 2,529 feet from the north line (FNL) and approximately 617 feet from the west line (FWL) of Section 21, to a bottom hole location at approximately 1,100 FNL and 66 feet FWL in said Section 21, within Township 26 South, Range 36 East, Lea County, New Mexico.
- 4. The proposed injection zone for the Titan AGI #4 well will target the geologic formations of the Siluro-Devonian, including the Devonian, Wristen, and Fusselman formations, between depths of approximately 17,570 to 19,130 feet.
- 5. The injection stream will consist of TAG comprised of approximately 80 percent carbon dioxide and 20 percent hydrogen sulfide from oil and gas wells in the area.
- 6. The proposed maximum allowable operating pressure ("MAOP") requested for the Titan AGI #4 is approximately 5,811 psig. At the anticipated bottom-hole conditions of 250 °F and 8,300 psi, each MMSCF of TAG will occupy a reservoir volume of approximately 383 barrels.
- 7. Upon approval, the Titan AGI #4 well will be the second deep (i.e., Siluro-Devonian) AGI well at the Facility, and as such, it is proposed that the requested 28.8 MMSCFD reflect a combined allowable injection volume to be shared with the approved Salt Creek AGI #2

well, currently authorized to inject up to 12 MMSCFD under Order No. R-20913-D, as amended, and SWD-2622. In total, after the Titan AGI #4 well is approved, there will be three service-ready AGI wells to accommodate gas disposal to reduce waste and field flaring in the event any one well experiences downtime.

8. Approving this application will avoid the drilling of unnecessary wells, prevent waste, and protect correlative rights.

WHEREFORE, Northwind Midstream Partners LLC requests that this application be set for a status conference before the Oil Conservation Commission on October 17, 2024, and, after notice and hearing as required by law, the Commission enter an order approving this application.

Respectfully submitted,

ATTORNEYS FOR NORTHWIND MIDSTREAM PARTNERS LLC

CASE :

Application of Northwind Midstream Partners LLC for Approval of an Additional Redundant Acid Gas Injection Well and to Amend Order No. R-20913, As Amended, and SWD-2622 to Authorize an Increased Shared Maximum Daily Injection Rate, Lea County, New Mexico. Applicant in the above-styled cause seeks an order (1) authorizing injection of treated acid gas ("TAG") for purposes of disposal into the proposed Titan AGI #4 well as an additional redundant acid gas injection ("AGI") well, and (2) to further amend Order No. R-21093-D, as amended, and SWD-2622 to authorize a shared maximum daily injection rate of 28.8 million standard cubic feet per day (MMSCFD) of TAG for disposal through either or both its permitted Salt Creek AGI #2 well (API No. 30-025-53388) or the proposed Titan AGI #4 well. The proposed Titan AGI #4 well will be drilled as a deviated well with a surface location of approximately 2,529 feet from the north line (FNL) and approximately 617 feet from the west line (FWL) of Section 21, to a bottom hole location at approximately 1,100 FNL and 66 feet FWL in said Section 21, within Township 26 South, Range 36 East, Lea County, New Mexico. Injection will be into the Silurian-Devonian formations at depths of between approximately 17,570 to 19,130 feet below the ground through an open-hole completion. The injection stream will consist of TAG comprised of approximately 80 percent carbon dioxide and 20 percent hydrogen sulfide from oil and gas wells in the area. The proposed maximum allowable operating pressure ("MAOP") requested for the Titan AGI #4 is approximately 5,811 psig. The subject well will be located approximately 7.5 miles southwest of Jal, N.M.

FORM C-108 Revised June 10, 2003

APPLICATION FOR AUTHORIZATION TO INJECT

												
I.	PURPOSE: Secondary Recovery Pressure Maintenance X Disposal Storage Application qualifies for administrative approval? Yes X No											
II.	OPERATOR: Northwind Midstream Partners, LLC [331501]											
	ADDRESS: 811 Louisiana St, Suite 2500, Houston, TX 77002											
	CONTACT PARTY: Ben Ahiabor PHONE: (346) 613-1451											
III.	WELL DATA: Complete the data required on the reverse side of this form for each well proposed for injection. Additional sheets may be attached if necessary.											
IV.	Is this an expansion of an existing project?YesXNo If yes, give the Division order number authorizing the project:											
V.	Attach a map that identifies all wells and leases within two miles of any proposed injection well with a one-half mile radius circle drawn around each proposed injection well. This circle identifies the well's area of review. Section 5; Appendix A											
VI.	Attach a tabulation of data on all wells of public record within the area of review which penetrate the proposed injection zone. Such data shall include a description of each well's type, construction, date drilled, location, depth, record of completion, and a schematic of any plugged well illustrating all plugging detail. Section 5; Appendix A											
VII.	Attach data on the proposed operation, including:											
	 Proposed average and maximum daily rate and volume of fluids to be injected; Sections 1, 2, 3 Whether the system is open or closed; Sections 1, 2, 4 Proposed average and maximum injection pressure; Sections 1 & 3 Sources and an appropriate analysis of injection fluid and compatibility with the receiving formation if other than reinjected produced water; and, Sections 3 & 4 If injection is for disposal purposes into a zone not productive of oil or gas at or within one mile of the proposed well, attach a chemical analysis of the disposal zone formation water (may be measured or inferred from existing literature, studies, nearby wells, etc.). 											
*VIII.	Attach appropriate geologic data on the injection zone including appropriate lithologic detail, geologic name, thickness, and depth. Give the geologic name, and depth to bottom of all underground sources of drinking water (aquifers containing waters with total dissolved solids concentrations of 10,000 mg/l or less) overlying the proposed injection zone as well as any such sources known to be immediately underlying the injection interval. Section 4											
IX.	Describe the proposed stimulation program, if any.											
*X.	Attach appropriate logging and test data on the well. (If well logs have been filed with the Division, they need not be resubmitted).											
*XI.	Attach a chemical analysis of fresh water from two or more fresh water wells (if available and producing) within one mile of any injection or disposal well showing location of wells and dates samples were taken. Section 4											
XII.	Applicants for disposal wells must make an affirmative statement that they have examined available geologic and engineering data and find no evidence of open faults or any other hydrologic connection between the disposal zone and any underground sources of drinking water. Section 7											
XIII.	Applicants must complete the "Proof of Notice" section on the reverse side of this form. Appendix B											
XIV.	Certification: I hereby certify that the information submitted with this application is true and correct to the best of my knowledge and belief.

1.0 EXECUTIVE SUMMARY

On behalf of Northwind Midstream Partners, LLC (Northwind; OGID #331501), Geolex, Inc.® (Geolex) has prepared and is hereby submitting a complete C-108 application for approval to drill, complete, and operate an additional redundant acid gas injection (AGI) well in Section 21, Township 26 South, Range 36 East, approximately 7.5 miles southwest of the city of Jal, in Lea County New Mexico (Figure 1). The proposed well, Titan AGI #4, will provide additional redundancy with respect to acid gas disposal operations at the existing Titan Treating Facility, which is currently serviced by a shallow Delaware Mountain Group AGI well (Salt Creek AGI #3; API: 30-025-51865), and upon the completion of drilling activities, the approved Salt Creek AGI #2 well.

The proposed Titan AGI #4 well is designed to address the increasing sour-gas disposal needs of the Titan Treating Facility and local operators and will provide a redundant deep AGI well at the Northwind Titan Treating Facility (the Titan Facility). In submitting this application, Northwind seeks approval to dispose of up to 28.8 million standard cubic feet per day (MMSCFD), equivalent to approximately 13,760 barrels per day, of treated acid gas (TAG) into the Siluro-Devonian formation for at least 30 years. Upon approval, the Titan AGI #4 well will be the second deep (i.e., Siluro-Devonian) AGI well at the Titan Treating Facility, and as such, it is proposed that the requested 28.8 MMSCFD reflect a combined allowable injection volume to be shared with the approved Salt Creek AGI #2 well, currently authorized to inject up to 12 MMSCFD by New Mexico Oil Conservation Commission (NMOCC) Order 20913 (A-D).

The proposed TAG stream is anticipated to be comprised of approximately 80% carbon dioxide (CO₂) and approximately 20% hydrogen sulfide (H₂S), with trace concentrations (less than 1%) of hydrocarbons (C₁-C₇). When operating at full capacity, the Siluro-Devonian AGI wells (i.e., the proposed Titan AGI #4 and existing Salt Creek AGI #2) will permanently sequester approximately 1,169 tons of carbon dioxide (CO₂) and approximately 388 tons of hydrogen sulfide (H₂S) daily.

To minimize interference and ensure access to quality reservoir, Titan AGI #4 will be drilled as a deviated well with a surface location of approximately 2,529 feet from the north line (FNL) and approximately 617 feet from the west line (FWL) of Section 21 (T26S, R36E). The well will be directionally drilled to a bottom hole location at approximately 1,100 FNL and 66 feet FWL in Section 21 (T26S, R36E). To ensure adequate isolation of groundwater resources, producing intervals, and potential high-pressure depth intervals, Titan AGI #4 will be constructed utilizing a five-string casing design and all casing strings will be cemented to the surface. The integrity of cementing operations will be verified via visual inspection, as well as the collection of radial cement bond logs for all casing strings underlying the surface casing. The production casing and injection tubing will utilize approximately 300 feet of corrosion resistant alloy (CRA) materials in order to protect the well and lower well components from potentially corrosive conditions.

The proposed injection zone will target geologic formations of the Siluro-Devonian, including the Devonian, Wristen, and Fusselman formations, between depths of approximately 17,570 to 19,130 feet. Analyses of these geologic units confirm that they act as excellent closed-system reservoirs that will accommodate the increasing acid gas disposal needs of Northwind (and local operators) for the disposal of acid gas and sequestration of CO₂ from the Northwind Titan Treating Facility. As proposed, the Titan AGI #4 well will further enhance operational redundancy at the Northwind facility, in accordance with the original objectives of NMOCC Order R-20913 (A-D), as it will be a second redundant AGI well incorporated into the operations at the Titan Treating Facility. In total, there will be three service-ready AGI wells to accommodate gas disposal, in order to prevent waste and field flaring in the event any one well experiences downtime.

In the area of Titan AGI #4, the proposed injection interval is overlain by the Woodford Shale (over 400 feet thick), which serves as the primary upper confining layer. Additionally, up to 845 feet of tight carbonates in the Barnett and Osage formations overly the Woodford Shale and provide a significant interval of secondary confining strata. These units, in total, will provide more than 1,600 feet of confining strata that will sufficiently contain and prevent the upward migration of TAG. Within the project area, the closest active pay zone lies approximately 3,350 feet above the proposed injection zone in the Strawn Formation. The distance from active producing zones as well as the thick caprock ensures production will be unaffected by TAG injection via the Titan AGI #4 well. Additionally, the low porosity intervals of the underlying Montoya Formation carbonates and Simpson Group strata will prevent downward migration into underlying geologic strata.

The proposed maximum allowable operating pressure (MAOP) requested for the Titan AGI #4 is approximately 5,811 psig, which was determined by utilizing appropriate NMOCD-approved calculation methods that consider the specific gravity of the acid gas injection stream. At the anticipated bottom-hole conditions of 250 °F and 8,300 psi, each MMSCF of TAG will occupy a reservoir volume of approximately 383 barrels.

As it is critical to verify that the proposed Siluro-Devonian injection reservoir can accommodate the requested 28.8 MMSCFD of TAG, within reasonable operating pressure limitations, a detailed geologic analysis of the project area has been completed. This analysis, which leverages three dimensional (3D) seismic survey data, is the basis for which geologic reservoir modeling and injection simulation investigations have been completed. Analysis of these data has allowed for a detailed characterization of subsurface structure in the project area, and through seismic inversion analysis methods, detailed characterization of the proposed Siluro-Devonian injection reservoir, with respect to porosity development and the interconnectivity of porous strata, has been completed. Subsequent injection simulations completed to support this C-108 application clearly demonstrate that the proposed injection reservoir is fully capable of accommodating TAG injection up to 28.8 MMSCFD.

In accordance with the results of detailed geologic analyses, informed by 3D seismic survey data, reservoir modeling and injection simulations have been completed to better understand and forecast plume characteristics and the migration of the resultant TAG plume after 30 years of injection operations. Following operation of the Titan AGI #4, concurrently with Salt Creek AGI #2, as proposed, the resultant TAG plume will occupy a maximum area of approximately 5.2 square miles and would extend a maximum of approximately 1.8 miles north from the Titan Treatment Facility. Gas saturation values are anticipated to range from approximately 0 to 0.55 with diffuse concentrations (i.e., less than 10%) characterizing the plume margins. Comparison of these results to the locations of existing wells penetrating the Siluro-Devonian demonstrates that the migrating plume is not anticipated to encounter any nearby open wellbores, and thus, these wells are not anticipated to be impacted by the proposed operations of the Titan AGI #4 well.

To evaluate the potential for induced seismicity in response to injection operations, at the proposed rate of up to 28.8 MMSCFD, an induced seismicity risk assessment was completed. The analysis was completed utilizing the Stanford Center for Induced and Triggered Seismicity's Fault Slip Potential (FSP) modeling platform. While analysis of 3D seismic survey data has produced a detailed characterization of faults within the project area, it should be noted that no faults exhibit offset sufficient to compromise the injection reservoir confining strata. Results of the FSP analysis, which considers operation of the Northwind AGI wells, as well as additional offset saltwater disposal (SWD) wells, demonstrates that operation of the deep AGI wells (i.e., Salt Creek AGI #2 and Titan AGI #4), as proposed, will not result in an elevated risk for injection-induced fault slip in the area.

Within the one-mile area of review (AOR) there are 101 wells, which commonly were completed to produce shallow Tansill-Yates-Seven Rivers plays and deeper Bone Spring and Wolfcamp Formation plays. It should be noted that for the proposed Titan AGI #4, the one-mile area of review has been enhanced to include a one-mile buffer area comprising the surface location, bottom-hole location, and around the deviated well path. Of these 101 wells, 22 are active and 29 are plugged. Additionally, there are 32 locations permitted that have not yet been drilled or completed. Within a two-mile radius of the modified Titan AGI #4 AOR, there are four (4) plugged wells which penetrate the proposed Siluro-Devonian injection zone. These wells have been properly plugged and are not anticipated to be impacted by operation of the proposed Titan AGI #4 well, nor will they serve conduits for fluids to escape the injection zone. All relevant plugging reports and documents for these wells are included in Appendix A.

The area surrounding the proposed injection site is arid and there are no natural bodies of water within several miles of the Northwind Facility and proposed Titan AGI #4 well. A search of the New Mexico Office of the State Engineer's files shows 58 water wells or points of diversion within two miles of the proposed AGI surface- and bottom-hole locations. The closest water well is located approximately 0.6 miles away from the AGI #4 surface location and has been plugged. All wells within a two-mile radius are shallow and will be protected via the proposed Titan AGI #4 casing design, which includes a surface casing interval down to 2,120 feet that will isolate and protect all shallow groundwater resources.

In preparing this C-108 application, Geolex conducted a detailed examination of all the elements required to be evaluated in order to prepare and obtain approval for this application for Class II injection. The elements of the evaluation include:

- Identification and characterization of all hydrocarbon-producing zones of wells that surround and are present on the plant's site
- The depths of perforated pay intervals in those wells relative to the depth of the target injection zone (Siluro-Devonian interval)
- The past and current uses of the proposed injection interval
- The stratigraphic and structural setting of the targeted zones relative to any nearby active or plugged wells, and other wells penetrating the interval
- The identification of and sample notification letter that will be sent to all surface owners, lessees, and operators within a one-mile radius of the proposed injection well
- Identification and characterization of all plugged and operating wells penetrating the proposed injection zone within a one-mile radius of the proposed injection well
- The details of the proposed injection operation, including general well design and average maximum daily rates of injection and injection pressures
- An analysis of the potential for induced seismicity based on seismic review and mapping in the area
- Reservoir injection simulations to evaluate the resultant effects of injection operations in the area after 30 years at the maximum daily injection rate and predict the resultant acid gas dispersion area and saturation characteristics
- Sources of injection fluid and compatibility with the formation fluid of the injection zone

Location and identification of any freshwater-bearing zones in the area; the depth and quality of
available groundwater in the vicinity of the proposed well, including a determination that there
are no structures which could possibly communicate the disposal zone with any known sources of
drinking water

Based upon this detailed evaluation, Northwind has determined that the proposed Titan AGI #4 well is a safe and environmentally sound project for the disposal of TAG. Furthermore, our analyses demonstrate that the proposed injection well will not negatively affect any waters of the State, nor have any actual or potential impacts on production in the area. This application is fully protective of correlative rights.

2.0 INTRODUCTION AND ORGANIZATION OF THE C-108 APPLICATION

The completed NMOCD Form C-108 is included before the Table of Contents of this document and references appropriate sections where data required to be submitted are included.

This application organizes and details all of the information required by NMOCD and NMOCC to evaluate and approve the submitted Form C-108 – Application for Authorization to Inject. This information is presented in the following categories:

- A detailed description of the location, construction, and operation of the proposed Titan AGI #4 injection well (Section 3.0)
- An overview of the acid gas characteristics and modeling simulation results to predict the resultant acid gas plume and reservoir pressure effects from injection operations in the area of the proposed AGI well (Section 4.0)
- A summary of the regional and local geology, hydrogeology, and the location of drinking water wells within the area of review (Section 4.0)
- The identification, location, status, producing zones, and other relevant information on oil and gas wells within the area of review (Section 5.0)
- The identification and required notification for operators and surface landowners that are located within the area of review (Section 6.0)
- An affirmative statement, based on the analysis of geological conditions at the site that there is no hydraulic connection between the proposed injection zone and any known sources of drinking water (Section 7.0)

In addition, this application includes the following supporting information:

- **Appendix A:** Data tables showing all active, temporarily abandoned, abandoned, and plugged oil and gas wells within a two-mile radius and within the one-mile area of review, as well as associated plugging documents for relevant wells within two miles.
- **Appendix B:** Tables summarizing the operators, lessees, and surface owners in the one-mile radius area of review, an example of the notification letter that will be provided no less than 20 days prior to the NMOCC hearing, and a draft public notice.
- **Appendix C:** Request letter for permission to sample and analyze groundwater and proof of mailing documents (USPS Certified Mail).

3.0 PROPOSED CONSTRUCTION AND OPERATION OF TITAN AGI #4

Titan AGI #4 is intended to service Northwind's Titan Treatment Facility and will be constructed on the facility property in Section 21 of Township 26 South, Range 36 East, approximately 7.5 miles from the city of Jal, in Lea County, New Mexico (Figure 1). The well will be drilled as a deviated well from the surface geographic coordinates 32.029089, -103.276608 (NAD83) to a bottom-hole location approximately 1,532 feet to the northwest at 32.033013, -103.278384 (NAD83), as shown in Figure 2.

TAG to be injected via Titan AGI #4 will be routed from the adjacent Titan Treating Facility to on-site compression facilities that will compress and dehydrate the acid gas. The compressed TAG will then be transmitted to the AGI #4 injection tree via high-pressure, NACE-compliant piping for injection. AGI design details are provided in the following Sections 3.1 and 3.2.

3.1 PROPOSED DESIGN OF TITAN AGI #4

The location of the proposed Titan AGI #4 well and other facility AGI wells are shown in Figure 2, and a general schematic of the injection system is shown in Figure 3. The Titan AGI #4 well will be drilled to a total depth of approximately 19,130 ft MD (measured depth) within the Fusselman Formation. The injection interval (approximately 17,570 to 19,130 feet) will be completed as an open-hole injection interval that includes the Devonian, Wristen, and Fusselman formations.

The AGI facilities and well will be integrated components of the Northwind Titan Treating Facility design and the proposed Titan AGI #4, combined with the approved Salt Creek AGI #2 and #3 wells, will provide significant operational redundancy, with respect to acid gas disposal operations at the facility. The preliminary well design for the Titan AGI #4 well is shown in Figure 4.

Titan AGI #4 will utilize a five-string casing design to ensure the protection and isolation of shallow groundwater resources, oil and gas producing intervals, potential intervals of high-pressure conditions, and potential intervals of lost circulation. The surface casing (24-inch) will be set at approximately 2,120 feet, within the Rustler Formation to isolate shallow groundwater resources of the Dockum Group. The first intermediate casing string (18 5/8-inch) will be set at approximately 3,660 feet, to cement and isolate units overlying the Capitan Reef. The second intermediate casing string (13 3/8-inch) will provide isolation of the Capitan Reef, a known and confirmed interval of lost circulation, and be set at approximately 5,590 ft, overlying strata of the Delaware Mountain Group. The third intermediate casing string will be 9 5/8-inches and will be set within the Wolfcamp Formation at approximately 11,820 ft. MD to aid in the isolation of the lower pressured Delaware Mountain Group and Bone Spring Formation from the underlying, higher-pressure zones of the Wolfcamp, Strawn, Atoka, and Morrow formations. The production casing will utilize 7-inch casing and will be set in a competent geologic unit within the Devonian at an approximate depth of 17,570 ft. The injection interval will be drilled as a 5 7/8-inch open hole interval to a depth of approximately 19,130 ft. in the lower Fusselman Formation.

As shown in Figures 3 and 4, the Titan AGI #4 well design will include a subsurface safety valve (SSSV) on the production tubing to ensure that injected fluids are prevented from flowing back out of the well in the event of a failure of injection equipment. Additionally, the annular space between the production tubing and the wellbore will be filled with an inert fluid (i.e., corrosion-inhibited diesel fuel with biocide additives) as a further safety measure. These practices are consistent with injection well designs previously supported by NMOCD and approved by the NMOCC for acid gas injection and conform to industry best practices for AGI well design.

Design and material considerations for Titan AGI #4 include: (1) Placement of a corrosion-resistant subsurface safety valve to provide down-hole isolation and a CRA permanent packer; (2) installation of

multiple casing strings to isolate and protect shallow groundwater resources (Ogallala and Santa Rosa groundwater, Rustler Formation saline groundwater); (3) characterization of the zone of injection; and (4) a total depth ensuring accurate identification of the injection reservoir.

A suitable drilling rig will be selected for the job that will include an appropriately sized blowout preventer and choke-manifold system for any unforeseen pressures encountered, and operations to drill the Titan AGI #4 well will utilize a closed-loop system to manage drilling fluids. Visual inspection of cement returns to the surface will be documented in cementing operations of all casing strings, and casing and cement integrity will be demonstrated by pressure testing and 360-degree cement bond logs recorded for each cement operation below the surface casing. A schematic of the proposed well is shown in Figure 4 and the anticipated Titan AGI #4 casing plan is summarized in Table 1.

Table 1. Titan AGI #4 proposed casing schedule

Casing	Hole Size	Csg. Size (in.)	Pounds Per Foot	Grade	Grade Thread		Bottom (ft.)				
	(in.)	SEE (1111)	1 01 1 000				(144)				
Proposed Casing Schedule											
Conductor	36	30	118	-	Welded	0	120				
Surface	26	24	186.4	X-56	XLF	0	2,120

Proposed Injection Tubing											
Tubing	N/A	3.5	10.2	SS-95	VAMTOP*	0	17,270				
Tubing (CRA)	N/A	3.5	10.2	G3 (CRA)	VAM*	17,270	17,570				

^{*}Or equivalent gas-tight, premium thread connections

All casing strings will be cemented to the surface using appropriate conventional cement methods. The adequacy of cementing operations will be confirmed through pressure testing of the casing and 360-degree cement bond logs will be recorded after the required amount of time has passed for cement to set. Once the integrity of cementing operations has been verified, drilling of the next casing interval will commence.

In accordance with AGI well best construction practices, acid resistant cement slurries and/or CRA casing will be utilized along key depth intervals in which corrosive conditions may potentially be present. For the proposed Titan AGI #4 well, this includes the strategic use of acid resistant cement (e.g., Halliburton WellLock Resin, LockCem, or equivalent) across the Delaware Mountain Group, to ensure well integrity across an active acid gas disposal zone, and the incorporation of CRA casing, tubing, and acid-resistant cement at the base of the 7-inch production casing to protect lower well components and ensure well integrity. Depth intervals which incorporate acid-resistant cement slurries will utilize cement diverter tools (DVT) and external casing packers (ECP) to ensure successful placement and bonding of acid resistant cement, where required. Table 2 summarizes the preliminary cementing program for all Titan AGI #4 casing strings.

Table 2. Titan AGI #4 proposed cementing program

Casing String	Stage #	Cement Type	No. of Sacks	Density (#/gal)	Coverage Interval

For the purposes of monitoring down-hole injection conditions and long-term evolution of the Siluro-Devonian injection reservoir, Titan AGI #4 will be completed with permanent down-hole pressure and temperature sensors installed on a mandrel immediately overlying the packer assembly. The associated sensor communication lines will be clamped to the injection tubing, within the annulus, through termination blocks on the injection tree, and to a surface control panel, which will directly transmit data to the facility control room for observation, analysis, and recording.

The SSSV will be installed on the 3 ½-inch injection tubing at a depth of approximately 150 feet and connected to the surface wellhead via a ¼-inch Inconel hydraulic line. From the surface, the line is run to a surface control panel through stainless steel line. The SSSV surface control panel will be integrated into the facility control system, such that the SSSV can be activated on-site, from the control room, or through an automated emergency shutdown (ESD) process. While additional isolation equipment will be incorporated into the Titan AGI #4 design (e.g., manual and automatic valves on injection tree), the SSSV is critical as it provides a subsurface isolation point, in the event physical damage to the wellhead or surface isolation points occurs.

The National Association of Corrosion Engineers (NACE) issues guidelines for metals exposed to various corrosive gases, such as those anticipated for this AGI well. For an H₂S-CO₂ stream of acid gas that is dewatered at the surface via successive stages of compression, down-hole components, such as the SSSV and packer should be constructed of Inconel 925 (or equivalent) grade materials. The CRA joints utilized in the Titan AGI #4 well will be constructed of a similar alloy, such as Sumitomo SM2550 (with 50% nickel content), G3, or other suitable material grade. Additionally, the gates, bonnets, and valve stems within the injection tree will also be nickel coated, in accordance with the requirements of a dry acid gas injection tree.

The remainder of the injection tree will be constructed of standard carbon steel components and outfitted with annular pressure gauges that report operating pressure conditions in real time to a gas-control center located remotely from the wellhead. In the case of abnormal pressures or any other situation requiring immediate action, the acid gas injection process can be stopped or diverted to AGI #2 or AGI #3 at the

compressor, and the wellhead can be shut in using a pneumatically operated wing valve on the injection tree. The SSSV provides a redundant safety feature to shut in the well in case the wing valve does not close properly. After the AGI well is drilled and tested to assure that it will be capable of accepting the proposed volume of injection fluid (without using acid gas), it will be completed with the approved injection equipment for the acid gas stream.

3.2 GEOPHYSICAL LOGGING

Prior to running the intermediate (1st, 2nd, and 3rd) and production casing strings, open-hole geophysical logging will be performed for the interval underlying the surface casing from approximately 2,120 to 19,130 feet. The proposed open-hole logging suite will consist of the following: Gamma ray, formation density, resistivity, neutron porosity, sonic porosity, and 360-degree caliper measurements with integrated borehole volume. Additionally, Fullbore Formation MicroImager (FMI) logs will be recorded along the proposed Siluro-Devonian injection interval, as well as the overlying caprock (i.e., Woodford Shale) to verify the integrity and confirm the capability of overlying strata to properly confine and permanently sequester the injected TAG. Porosity and permeability characteristics of the proposed injection zone and overlying caprock strata will be further verified through collection and analysis of sidewall cores.

3.3 RESERVOIR STIMULATION, TESTING, AND PRESSURE MONITORING

Upon the completion of geophysical logging for drilling, casing/cementing, and geophysical logging activities, reservoir stimulation and testing operations will be completed. These operations include a spotacid treatment to clean out the wellbore prior to reservoir testing, step-rate injection testing (SRT), followed by acid stimulation. In accordance with accepted stimulation procedures for AGI wells, the step-rate injection test will be conducted prior to acid stimulation activities, with the exception of low-volume, spot acid treatment to clean out and prepare the well for testing.

Prior to step-rate injection testing, a spot acid treatment will be performed in which approximately 3,000 gallons of 15% hydrochloric acid (HCl) will be displaced along the open-hole injection interval for approximately 24 hours, for the purposes of cleaning the wellbore of drilling fluids potentially invading porous intervals. Utilizing a temporary string comprised of a retrievable test packer and workstring tubing, a step-rate injection test will be performed to confirm the adequacy of injection pressure limitations and approved injection volume, and to ensure that the formation parting pressure (i.e., fracture pressure) is not reached during future TAG injection operations. Once the reservoir has been tested and safe operational conditions have been confirmed, the injection reservoir response to injection activities will be characterized through completion of a pressure fall-off test, in which the return to static pressure conditions is monitored via down-hole pressure gauges. Depending on actual reservoir porosity and permeability attributes, it is anticipated that fall-off testing activities will require approximately 3-10 days of down-hole monitoring.

Following the completion of reservoir testing activities (SRT and pressure fall-off monitoring), a complete acid stimulation of the open-hole interval will be completed. Approximately 40,000 gallons of 15% HCl and approximately 8,000 gallons of gelled 15% HCl acid will be injected into the reservoir to open potential reservoir-bound fractures, secondary porosity zones, and dissolve any natural carbonate cement within the pore spaces of the Siluro-Devonian injection zone. As needed, diverter materials (e.g., rock salt) will be utilized to divert acid volumes away from high-porosity intervals and ensure complete stimulation of the open-hole interval.

Upon the completion of reservoir testing and stimulation activities, the final tubing string and permanent injection packer will be run and set at an approximate depth of 17,540 feet. For long-term monitoring of down-hole conditions, Titan AGI #4 will be equipped with bottom-hole pressure and temperature

instrumentation designed to provide real-time monitoring of reservoir conditions, as it is installed immediately above the permanent injection packer. While this equipment is useful in gathering data that will ultimately be used to evaluate reservoir and well performance, it is only a portion of the overall data collection and analysis program to evaluate the reservoir over time and to compare the predicted reservoir performance (discussed in Sections 4.6 and 4.7) with actual performance in future reporting periods.

The collection and analysis of injection and annular pressure data has a two-fold purpose. First, to provide an early warning of any mechanical well integrity issues that may arise, and the second to provide data for reservoir performance evaluation. While the initial purpose of monitoring the mechanical integrity of the well only requires the surface injection pressure, temperature, rate, and annular pressure monitoring, the bottom-hole data provides the ability to analyze and evaluate the performance of the Siluro-Devonian injection reservoir.

Surface pressure/temperature/annular pressure monitoring equipment has extremely high reliability, whereas our experience with bottom-hole pressure/temperature monitoring equipment has shown that this equipment is more complex and may suffer from periodic data collection and transmission issues. As such, we have developed a process to ensure that necessary data are collected in the event of bottom-hole sensor failure. The simultaneous collection of the surface- and bottom-hole data allows for the development of empirical relationships with actual observed data that, in conjunction with the use of established models (such as, AQUAlibriumTM, or equivalent) will allow data gaps to be filled when bottom-hole data loss occurs. This approach will allow us to provide NMOCD with reliable monitoring data and interpretations that provide the basis for reservoir evaluation performed periodically during the life of the Titan AGI #4 well.

Below is a summary of the overall data collection and analysis program proposed for this well and injection reservoir:

- 1. Obtain measurements of initial bottom-hole pressure and temperature after drilling (during logging)
- 2. Perform detailed step-rate injection test and pressure fall-off test to provide baseline reservoir conditions prior to the commencement of TAG injection activities
- 3. Monitor surface parameters (injection pressure, temperature, injection rate, and annular pressure) to provide an early warning system for any potential mechanical integrity issues in the well
- 4. Monitor bottom-hole pressure and temperature with permanent sensors to provide real-time reservoir conditions for analysis of reservoir performance
- 5. Use bottom-hole reservoir and surface pressure and temperature data to develop a well-specific empirical relationship between observed surface- and bottom-hole conditions
- 6. Use TAG/wellbore model to predict bottom-hole conditions based on surface data and test with empirical relationships observed in #5 above to calibrate models
- 7. Use surface data along with protocols described above to fill in missing bottom-hole data when data gaps or sensor failure occurs
- 8. In the event of an extended period of bottom-hole pressure/temperature sensor failure, perform periodic bottom-hole pressure monitoring using slickline pressure gauges when data from such temporary device is necessary to fill in data for relevant reservoir analysis

9. After approximately ten (10) years of operation, perform another detailed step-rate injection test and fall-off test to compare with baseline conditions prior to the commencement of TAG injection

3.4 INJECTION STREAM CHARACTERISTICS AND MAXIMUM ALLOWABLE OPERATING PRESSURE

The proposed Titan AGI #4 well has been designed and will be constructed such that it can be safely operated as an acid gas injection well to dispose of a mixed stream of TAG containing H₂S and CO₂. Based on current gas-treatment forecasting, the TAG stream is anticipated to be comprised of the following constituents:

Carbon Dioxide (CO₂)
Hydrogen Sulfide (H₂S)
20%

- Trace Nitrogen and hydrocarbons (C₁-C₇) Less than 1%

The maximum total volume of TAG to be injected daily will be approximately 28.8 MMSCF per day, a volume proposed to be shared with the approved Salt Creek AGI #2 and reflective of a total daily volume limitation for Siluro-Devonian injection (via Titan AGI #4 and Salt Creek AGI #2). Pressure reduction valves and controls will be incorporated to ensure that the maximum surface injection pressure allowed by NMOCD will not be exceeded.

The specific gravity of TAG is dependent on the temperature and pressure conditions and the composition of the TAG mixture. It is most accurately calculated using a modification of the Peng-Robinson (PR) equation of state (EOS) model (Boyle and Carroll, 2002). We have calculated the specific gravity of the supercritical TAG phase for the proposed Titan AGI #4 well using the AQUAlibriumTM 3.1 software, which employs the modified PR EOS model (Table 3).

We have modeled the proposed maximum daily injection rate of 28.8 MMSCF per day composed of 80% CO₂ and 20% H₂S. Specific gravities of TAG were determined for the conditions at the wellhead (1,700 psi, 110 °F), the total depth of the well (8,300 psi, 250 °F), and under average reservoir conditions (see Table 3).

To determine the proposed maximum surface injection pressure, we utilize the following NMOCD-approved method, which is based on the final specific gravity of the injection stream. Utilizing this method, we propose a maximum allowable operating pressure (MAOP) of approximately 5,811 psig, as determined by the following calculations:

MAXIMUM ALLOWABLE OPERATING PRESSURE (MAOP) DETERMINATION

$$IP_{Max} = PG(D_{Top})$$

Where: $IP_{Max} = Maximum Surface Injection Pressure (psi)$

PG = Pressure Gradient of Injection Fluid (psi/ft.)

 D_{Top} = Depth at top of perforated interval of injection zone (ft.)

And

$$PG = 0.2 + 0.433 (1.04 - SG_{Tag})$$

Where: $SG_{Tag} = Average specific gravity of treated acid gas in the tubing$

 $(SG_{Tag} \text{ at top} = 0.66, \text{ and } SG_{Tag} \text{ at bottom} = 0.82; \text{ see Table 3})$

For the maximum requested injection volume case, it is assumed that:

$$SG_{Tag} = 0.7381$$

 $D_{Top} = 17,570 feet$

Therefore:

$$PG = 0.2 + 0.433 (1.04 - 0.7381)$$

$$PG = 0.3307$$

And

$$IP_{Max} = 0.3299 \frac{psi}{ft} \times 17,570 ft$$

$$IP_{Max} = 5,811 psi$$

Based on this determination, Northwind requests approval for a surface injection MAOP of 5,811 psig for the proposed Titan AGI #4 well.

Table 3. Anticipated TAG stream characteristics at wellhead, bottom of well, and in reservoir at equilibrium conditions

4.0 REGIONAL AND LOCAL GEOLOGY AND HYDROGEOLOGY, RESERVOIR CHARACTERIZATION AND INJECTION SIMULATION

4.1 GENERAL GEOLOGIC SETTING AND SURFICIAL GEOLOGY

The proposed Titan AGI #4 well site is located in Section 21 of Township 26 South, Range 36 East, approximately 7.5 southwest of the city of Jal, in Lea County, New Mexico (Figure 1). The well's location lies on the eastern flank of the topographic Pecos River Basin within the Javelina Basin. Generally, the area is flat and covered predominantly by sand dunes overlying a hard caliche surface. The dunes are locally stabilized with shin oak, mesquite, and some burr grass. There are no observed surface bodies of water, or groundwater discharge sites within one mile of the proposed location. Where drainages exist in interdunal areas, they are ephemeral, discontinuous, dry washes. The proposed well site is underlain by Quaternary alluvium overlying the Triassic redbeds of the Santa Rosa Formation (i.e., Dockum Group), both of which are local sources of groundwater. The thick sequences of Permian rocks that underly these deposits are generally described below.

4.2 BEDROCK GEOLOGY

The Northwind Midstream Titan Treatment Facility and the proposed Titan AGI #4 well are located along the eastern margin of the Delaware Basin, a sub-basin of the larger, encompassing Permian Basin (Figure 5), which covers a large area of southeastern New Mexico and west Texas. The Permian as we know it today began to take form during the Middle to Late Mississippian, with various segments (Delaware Basin, Midland Basin, Central Basin Platform, and North Platform) arising from the ancestral Tabosa Basin. The Delaware Basin was subsequently deepened by periodic deformation during the Hercynian Orogeny of the Pennsylvanian through Early Permian. Following the orogeny, the Delaware Basin was structurally stable and was gradually filled by large quantities of clastic sediments while carbonates were deposited on the surrounding shelves and was further deepened via basin subsidence.

Figure 6 illustrates a generalized Permian Basin stratigraphic column showing the anticipated formations and lithologies that underly the proposed well site. The entire Lower Paleozoic interval (Ellenburger through Devonian) was periodically subjected to subaerial exposure and prolonged periods of karsting, most especially in the Fusselman and Devonian intervals. The result of this exposure was the development of systems of karst-related secondary porosity, which included solution-enlargement of fractures and vugs, and the development of small cavities and caves. Particularly in the Fusselman, solution features from temporally distinct karst events became interconnected with each successive episode of subaerial exposure, so there is the potential for vertical continuity in parts of the Fusselman that could lead to enhanced vertical and horizontal permeability.

The sub-Woodford Shale Paleozoic rocks extend down to the Ordovician Ellenburger Formation, which is separated from underlying basement rock by a limited interval of Early Ordovician sandstones and granite wash. The Ellenburger is comprised of dolomites and limestones and can be several hundred feet thick. It is overlain by approximately 880 feet of Ordovician Simpson Group sandstones, shale, and tight limestones, as well as approximately 480 feet of basal Montoya cherty carbonates. Tight carbonates and abundant interbedded shale deposits within the Montoya and Simpson group serve as the underlying confining strata for the proposed Siluro-Devonian injection reservoir.

The Silurian Fusselman, Wristen, and Devonian Thirtyone formations overly the Montoya Formation and are comprised of interbedded dolomites and dolomitic limestones that are capped by the Woodford Shale. The Woodford Shale is overlain by several hundred feet of tight Osagean limestone and several hundred feet of shale and basinal limestones of the Upper Mississippian Barnett Formation. The overlying Pennsylvanian Morrow, Atoka, and Strawn formations complete the pre-Permian section. Within this

entire sequence, wells have historically produced gas from the Strawn, however, gas production from Strawn in the area is limited to only one nearby producing well. Active oil and gas production within the area of review of the proposed AGI well is found predominantly in the Tansill-Yates-Seven Rivers pools and horizontal plays (active and permitted) within the Bone Spring and Wolfcamp formations. The deepest currently producing formation, the Strawn Formation, is approximately 3,300 feet above the target injection zone.

4.3 LITHOLOGIC AND RESERVOIR CHARACTERISTICS OF THE SILURO-DEVONIAN FORMATIONS

The proposed injection interval for the Titan AGI #4 well includes the Devonian Thirtyone and Silurian Wristen and Fusselman formations (collectively referred to as Siluro-Devonian). These strata are comprised of carbonates with high permeability such as porous limestones or dolostones with moderate porosity that are well-demonstrated as capable injection reservoirs by numerous saltwater disposal (SWD) and AGI wells in the basin. In evaluating the proposed Titan AGI #4 location, Geolex determined that the Devonian and Silurian injection reservoirs exhibited sufficient porosity potential to accommodate the disposal needs of the Northwind Midstream Titan Treatment Facility. Additional discussion regarding the evaluation of Siluro-Devonian reservoir characterization is included in Section 4.6.

Based on the geologic analysis of the subsurface, acid gas injection and CO₂ sequestration is recommended between the depths of approximately 17,570 feet to 19,130 feet. The proposed injection zone consists of approximately 1,560 feet of Siluro-Devonian strata, comprised predominantly of porous carbonates (resulting from numerous subaerial exposure events) that would readily accept TAG for permanent sequestration. Figure 7 includes an interpreted type log, showing the lithology of the subsurface formations and anticipated formations are included in Table 4.

The primary caprock for the Siluro-Devonian injection reservoir is the upper Devonian Woodford Shale, approximately 370 feet thick in this area. The Woodford Shale is overlain, in turn, by approximately 845 feet of tight shales and carbonates of the Barnett and Osage formations. These units provide an excellent geologic seal above the porous carbonates of the injection zone, ensuring that overlying pay intervals and shallow groundwater resources are adequately isolated from the proposed injection zone.

Figure 8 shows a structural contour map covering the area of the proposed Titan AGI #4 well and Figure 9 includes a structural cross section (A-A') which highlights the lateral extent of available Siluro-Devonian porosity and regional coverage of the overlying Woodford Shale caprock. The proposed AGI well location is on the southwestern-dipping slope and there is no indication of faulting that offsets the lateral continuity of injection reservoir confining strata. Geophysical logs from included wells indicate several intervals within the proposed injection zone exhibit significant porosity development and the anticipated low-porosity and low-permeability caprock is shown to be laterally continuous within the greater project area.

Table 4. Anticipated formation tops at the proposed Titali AO1 #4 location							
Formation	Depth (MD)	Formation	Depth (MD)

4.4 CHEMISTRY OF SILURO-DEVONIAN RESERVOIR FLUIDS

A review of formation waters from the U.S. Geological Survey National Produced Water Geochemical Database, v. 2.3 identified six wells with analyses from drill stem test fluids collected from the Devonian-Silurian interval in wells within approximately 15 miles of the proposed Titan AGI #4. Table 5 below summarizes the measured formation fluid characteristics.

Table 5. Summary of produced water analyses from nearby wells (U.S. Geological Survey National Produced Water Geochemical Database, v. 2.3)

API	Concentration (parts per million)							
API	TDS	HCO ₃	Ca	Cl	Mg	Na	SO ₄	
30-025-12386	56776	66	5407	35590	1333	14380	N/A	
30-025-11886	101036	540	5393	61630	2183	N/A	910	
30-025-11818	27506	1089	1384	15270	540	N/A	1079	
30-025-24464	108837	188	5659	65493	1051	34834	1613	
30-025-11863	158761	476	17240	100300	5345	N/A	N/A	
30-025-11950	31931	302	7196	20450	2241	N/A	591	

These analyses show Total Dissolved Solids (TDS) in the area of the proposed AGI well ranging from 31,931 to 158,761 parts per million (PPM) with an average of 80,808 PPM. The primary constituent in the sampled formation waters is the chloride ion, with an average concentration of 49,455 PPM.

Based on these data, the Siluro-Devonian reservoir fluids are anticipated to be completely compatible with the acid gas injectate, however, an attempt will be made to sample formation fluids during drilling and completion of the proposed Titan AGI #4 to provide more site-specific fluid properties and verify our assessment of fluid compatibility.

4.5 GROUNDWATER HYDROLOGY IN THE VICINITY OF THE PROPOSED AGI WELL

Based on the New Mexico Water Rights Database from the New Mexico Office of the State Engineer, there are 58 water wells or points of diversion located within a two-mile radius of the Titan AGI #4 surface- and bottom-hole location, and 14 water wells within one mile. Of these wells, the closest is located approximately 0.61 miles to the south of the Titan AGI #4 surface-hole location (Figure 10; Table 6). All wells within the two-mile radius are relatively shallow, with depths ranging from approximately 100 feet to 1,000 feet in alluvium and Triassic redbeds. Shallow groundwater resources will be fully protected by multiple strings of telescoping casing, all of which will be cemented back to surface. As

illustrated in Figure 4, design considerations for the Titan AGI #4 well include a five-string casing design, including a surface casing interval that extends to approximately 2,120 feet within the Rustler Formation, effectively isolating shallow groundwater resources.

The area surrounding the proposed injection well is arid and there are no bodies of surface water within a two-mile radius.

Table 6. Water wells or points of diversion within one mile of the Titan AGI #4 surface- and bottom-hole locations (Retrieved from the New Mexico Office of the State Engineer's Files on May 1, 2024)

In lieu of recent groundwater sample collection and chemical analysis, Geolex conducted a review of *Geology and Ground-Water Conditions in Southern Lea County, New Mexico* (Nicholson and Clebsch, 1961) to identify published groundwater data representative of nearby water wells in the area (within less than 10 miles) of the proposed Titan AGI #4 well. Table 7 summarizes the four wells identified in this review and the results of those chemical analyses.

Our analysis confirms that the proposed well poses no risk of contaminating groundwater in the area as (1) the proposed well design includes material considerations to protect shallow groundwater resources and multiple casing strings that provide redundant physical barriers isolating groundwater, and (2) there are no identified conduits that would facilitate migration of injected fluids to freshwater-bearing depth intervals.

4.6 RESERVOIR CHARACTERIZATION TO SUPPORT GEO-MODELING AND INJECTION SIMULATION ASSESSMENT

As it is critical to verify that the proposed Siluro-Devonian injection reservoir can accommodate the requested 28.8 MMSCFD of TAG, within anticipated surface operating pressure limitations, Northwind has completed detailed reservoir characterization, reservoir modeling, and injection simulation evaluations, which leverage licensed three dimensional (3D) seismic survey data. Analysis of these data has allowed for the development of a reservoir characterization model, refinement of previous geologic structure and fault interpretations, and through seismic inversion analysis methods, a detailed characterization of Siluro-Devonian porosity development and the interconnectivity of porous strata. Subsequent injection simulations clearly demonstrate the proposed Siluro-Devonian injection reservoir is capable of accommodating TAG injection up to 28.8 MMSCFD.

In completing geologic analysis of the project area, Northwind has licensed approximately 18 square miles of 3D seismic survey data. Analysis, interpretation, and reprocessing of these data forms the basis in confirming the Siluro-Devonian injection reservoir's capability of accommodating TAG injection up to 28.8 MMSCFD. Specifically, derivative data yielded from high-resolution seismic trace inversion methods, have allowed Northwind to more accurately characterize porosity development within the Siluro-Devonian geologic strata. Being sourced from 3D seismic data, the result of this analysis provides critical information regarding not only porosity development, but also the vertical and lateral continuity and interconnectivity of porous strata.

From seismic survey analysis, significant porosity development produced from karst dissolution processes is apparent and is highly interconnected across the greater project area. As anticipated, porosity development is most significant in the depth intervals of the upper Devonian and Fusselman formations strata. Based on mapped acoustic impedance attributes, which are directly related to porosity within the

injection reservoir, Siluro-Devonian porosity attributes were determined to range from less than 1% to approximately 8%, with an average porosity of 2.1%. Impedance attributes derived from high-resolution seismic trace inversion were transformed to porosity through direct correlation with log porosity, and the transform function was limited to maximum porosity measurements observed in wireline porosity logs.

In addition to providing a more accurate characterization of reservoir attributes, the analysis of seismic survey data yields a better understanding of subsurface faults and reservoir geometry within the project area. Figure 11 includes a map of fault features interpreted through the analysis of seismic data. Generally, faults within the project area trend north to south or approximately east to west. In total, 13 faults are interpreted, which have been further subdivided into 24 fault segments, for the purposes of evaluating induced seismicity risk (discussed in Section 4.9). For all interpreted faults, the magnitude of offset (or fault throw) is less than the thickness of the Woodford Shale confining strata, and thus, does not compromise the ability to contain TAG within the proposed Siluro-Devonian injection reservoir.

From our review and analysis of seismic survey data, a reservoir characterization model was developed to be utilized for injection simulation investigations that assess the feasibility of TAG injection up to 28.8 MMSCFD and shared by the approved Salt Creek AGI #2 well and the proposed Titan AGI #4 well. The results of these case simulations are discussed further in Section 4.7 and confirm the capability of the Siluro-Devonian injection reservoir in accommodating TAG injection volumes, as proposed and requested by Northwind.

4.7 ACID GAS INJECTION MODELING AND SIMULATION

To simulate the proposed injection scenario and characterize the resultant TAG injection plume, after 30 years of operation at the maximum daily injection rate of 28.8 MMSCFD, Geolex collaborated with Sproule to develop a reservoir characterization model and complete updated injection simulations, informed by and incorporating the recently acquired seismic survey data and resultant mapped porosity attributes. This modeling evaluation was completed utilizing Schlumberger Petrel to construct a geologic simulation grid informed by available well log data and mapped seismic impedance attributes, which are directly related to porosity within the injection reservoir. Schlumberger's Eclipse platform was then utilized to complete injection simulations representative of the injection scenario proposed for the Titan AGI #4 and approved Salt Creek AGI #2 wells (up to 28.8 MMSCFD).

The reservoir characterization model is comprised of 151 simulation layers characterizing eight discrete depth intervals identified within the Siluro-Devonian reservoir. In total, the model grid is comprised of 3,395,651 cells. The simulation model includes nearby subsurface fault features and the approved (but not yet drilled) Salt Creek AGI #2.

As described previously in Section 4.6, porosity attributes within the reservoir model are based on mapped acoustic impedance attributes, which directly relate to porosity within carbonate and dolomitic strata of the injection reservoir. Impedance attributes derived from high-resolution seismic trace inversion were transformed to porosity through direct correlation with geophysical log porosity and the range of porosity was limited to measurements observed in wireline logs. Utilizing this method, Siluro-Devonian reservoir porosity was determined to range from less than 1% to approximately 8%, with an average porosity of 2.1%. The distribution of porosity within the reservoir model is shown in Figure 12.

In defining permeability attributes, multiple data sources were utilized to identify baseline relationships between porosity and permeability, including injection reservoir test data, DST, injection well operating data, and published core-analysis data (e.g., Lucia et al., 1995). Permeability within the reservoir model, averaged by zone, ranges from 0.9 to 12.3 millidarcies (mD), with an average model permeability of 5.1 mD. The total model (all zones) permeability distribution is shown in Figure 12 and Table 8 below

summarizes geologic model zones defined, zone thickness, and average model porosity and permeability, by zone.

Table 8. Summary of geologic model zone thickness and model porosity and permeability attributes

Zone #	Thickness	Average Porosity (%)	Avg. Permeability
			(mD)
1	118	0.9	2.1
2	98	1.9	1.2
3	126	3.2	2.4
4	374	1.4	0.9
5	199	1.8	1.7
6	220	2.6	0.01
7	38	2.4	10.5
8	378	2.1	12.3

With the constructed geologic model, injection operations for the proposed Titan AGI #4 and approved Salt Creek AGI #2 wells were simulated (i.e., dynamic modeling) utilizing the Schlumberger Eclipse platform. Dynamic modeling was utilized to simulate injection of a mixed acid gas stream containing approximately 20% H₂S and 80% CO₂ at a constant rate of 28.8 MMSCFD. Reservoir pressure conditions initially reflect a normally pressured system (0.433 psi/ft.) and to ensure a conservative estimate of plume size, the injection simulations do not consider acid gas dissolution into existing formations.

In support of this C-108 application, two dynamic model simulations are presented, which estimate the size and characteristics of the resultant TAG injection plume, following operations of the AGI wells (Titan AGI #4 and Salt Creek AGI #2) at a shared daily injection volume of up to 28.8 MMSCFD. Case 1 reflects injection well operations in a subsurface environment in which faults are fully transmissive of fluids, while Case 2 considers faults to be non-transmissive of fluids. From these simulation end members, conservative estimates of plume size and migration directions are identified.

The results of Case 1 and Case 2 injection simulations are illustrated in Figures 13 and 14, for transmissive and non-transmissive faults, respectively. Following the 30-year injection period, the resultant TAG plume is anticipated to occupy an area of approximately 5.2 square miles generally extending up to 1.8 miles from the Titan Treatment Facility. For all case simulations, results indicate that injection operations, up to 28.8 MMSCFD, can be maintained for the complete simulation period. Furthermore, injection activities at the proposed daily rates are sustained within anticipated and currently approved surface injection pressure limitations.

4.8 POTENTIAL FOR VERTICAL MIGRATION OF ACID GAS TO OVERLYING PRODUCTIVE ZONES

Results of the injection system simulations predict that some fraction of acid gas injectate will exhibit a dispersion pattern such that gas reaches local fault features in the area. These features represent potential conduits for the vertical transmission of acid gas out of the target injection reservoir and into overlying productive zones. To address this concern, Geolex reviewed available drilling fluid records in the area of the proposed AGI. Additionally, published literature evaluating regional reservoir pressure conditions in the Delaware Basin was utilized. Based on this analysis, we determined these sealed faults could not result in an escape of TAG from the injection zone.

Illustrated in Figure 16 are wells and associated drilling fluid densities utilized while drilling through overlying producing zones in the area of the Titan AGI #4 well. Above the proposed Siluro- Devonian injection reservoir mud weights utilized range from 11.9 to 15.1 pounds per gallon (ppg). For those wells identified that penetrate the proposed injection reservoir, fluid records indicate utilization of less dense fluids (average of 9.0 ppg). These records support the interpretation that overlying producing zones in this area are over-pressured with respect to the target injection reservoir.

Over-pressured reservoir conditions within the Lower Bone Springs to Woodford formation strata have been recognized in many areas of the eastern Delaware Basin (Luo et al., 1994). Rittenhouse et al. (2016) generated a regional pore-pressure model of the Delaware Basin informed by over 23,700 drilling fluid recordings and more than 4,000 drill-stem and fracture injection tests. As shown in Figure 15, these compiled fluid records and testing operations indicate increased pore-pressure gradients from Lower Bone Springs to Woodford Formation strata expressed in the utilization of heavier drilling fluids. Normal pressure conditions are observed to return underlying the Woodford Shale.

Based on the record of local drilling fluids utilized and extensive records compiled by Rittenhouse et al. (2016), the proposed Siluro-Devonian injection reservoir at this location is anticipated to be underpressured with respect to overlying strata. Under these conditions, there is no potential for the vertical migration of acid gas out of the target reservoir as the pressure differential between the over- and underpressured intervals will act as a barrier impeding vertical migration, even along potential conduits.

4.9 INDUCED-SEISMICITY RISK ASSESSMENT

To evaluate the potential for seismic events in response to injected fluids, an induced-seismicity risk assessment was conducted in the area of the proposed Titan AGI #4 well. This estimate (1) Models the impact of five injection wells over a 30-year injection period, and (2) estimates the fault slip probability associated with the five-well injection scenario. The analysis was completed utilizing the Stanford Center for Induced and Triggered Seismicity's (SCITS) Fault Slip Potential (FSP) modeling package.

Based on the detailed review of seismic survey data (described previously in Section 4.6), Geolex identified 13 faults, located within approximately three miles of the Titan AGI #4, and generally striking north to south, and east to west (Figure 11). Due to the low number of wells in close proximity to these features and considering the relatively small injection volume proposed for the Titan AGI #4 well (equivalent to approximately 11,043 barrels per day and shared with AGI #2), operation of the Titan AGI #4 well, concurrently with the approved Salt Creek AGI #2 well, is not anticipated to contribute significantly to the risk for injection-induced fault slip. To verify these structures would not be adversely affected by operation of the AGI wells, as proposed, a model simulation was performed.

To calculate the fault slip probability for this injection scenario, input parameters characterizing the local stress field, reservoir characteristics, subsurface features, and injected fluids are required. Parameters utilized and their sources for this study are included in Table 9 below. Additionally, Table 10 and Figure 17 detail the injection volume characteristics and geographic locations of injection wells included in this assessment.

For this study, limitations of the FSP model require a conservative approach be taken in determining the fault slip probability of the four-well injection scenario. Specifically, the FSP model is only capable of considering a single set of fluid characteristics and this study aims to model a scenario that includes saltwater disposal (SWD) wells and acid gas injection wells. To ensure a conservative fault slip probability estimate, the proposed AGI well was modeled utilizing the fluid characteristics of produced water. This approach yields a more conservative model prediction as produced water displays greater

density, dynamic viscosity, and is significantly less compressible than acid gas. Characteristics of acid gas at anticipated reservoir conditions, as modeled by AQUAlibriumTM, are shown in Table 9.

Table 9. Input parameters and source material for FSP simulation

Modeled Parameter	Input Value	Variability (+/-)	UOM	Source

Daily maximum injection volumes utilized in the FSP model range from 4,265 to 20,000 bpd (Table 10). In submission of this application, Northwind is requesting approval to operate the proposed Titan AGI #4 well for a period of at least 30 years. This simulation includes a history matching period of six additional years to ensure the simulation results also consider the historical impact of injection wells that have been operating since 2019. Figure 18 shows the resultant pressure front, single well radial solutions, and the predicted pressure change at the fault segment midpoints; Figure 19 shows the model-predicted fault slip potential for all wells operating at maximum capacity. The predicted pressure change along each fault segment, model-derived pressure change to induce slip, and model-predicted actual pressure change are summarized in Table 11 below.

Table 10. Location and operating parameters of injection wells modeled in FSP assessment

#	API	Well Name	Latitude	Longitude	Volume	Start	End

14	2200	232	0.00
15	3851	256	0.00
16	1514	172	0.00
17	1652	143	0.00
18	6703	223	0.00
19	1894	262	0.00
20	1550	318	0.00
21	1167	96	0.00
22	6280	74	0.00
23	6354	71	0.00
24	4703	53	0.00

Generally, faults considered in this assessment are predicted by the FSP model to have very low potential for injection-induced slip and the proposed Titan AGI #4 is not predicted to contribute significantly to the total resultant pressure front. All faults within the modeled study area show no increase in slip probability throughout the 30-year scenario (Figures 18 and 19). Furthermore, radial pressure solutions calculated for each injection well illustrate that the operation of the proposed Titan AGI #4 well, and approved Salt Creek AGI #2 well, will have little impact pressure conditions near faults in the area.

5.0 OIL AND GAS WELLS IN THE TITAN AGI #4 AREA OF REVIEW AND PROJECT AREA

In support of this application, Northwind conducted a detailed review of the area within one-mile and two-miles of the proposed Titan AGI #4 location. This review is necessary to ensure all oil and gas operators and all interested parties have been identified, such that they can be provided notice of the NMOCC hearing to consider this matter and be provided complete copies of the C-108 application and request.

For the purposes of evaluating and identifying oil and gas activities, operators, and other interested parties within the project area, the one-mile Area of Review (AOR) is displayed as a one-mile buffer area around the surface- and bottom-hole location of the Titan AGI #4 well, and along the deviated wellbore path of Titan AGI #4.

5.1 OIL AND GAS WELLS IN THE TITAN AGI #4 AREA OF REVIEW

Appendix A summarizes in detail all NMOCD recorded wells within a one- and two-mile radius of the proposed Titan AGI #4. These wells are shown in Figure A-1 and include active, plugged, and permitted well locations. Table A-1 summarizes all wells within two miles of the proposed AGI well and wells located within one mile are included in Table 14 below.

In total, there are 83 wells within a one-mile radius of the proposed Titan AGI #4 surface- and bottom-hole locations. Specific information relating to active, new, and plugged wells is summarized in Appendix A and Table 12, and their geographic locations are shown in Figure 20. Of these wells, 22 are active and 29 have been plugged. Additionally, there are 32 locations permitted that have not yet been drilled or completed. Specific information relating to active and plugged wells is summarized. Active wells are primarily producing from the Tansill-Yates-Seven Rivers shallow depth intervals, as well as the Lower Bone Spring and Wolfcamp pools, all of which, overly and are isolated from the proposed injection zone.

Within two miles of the Titan AGI #4 well, there are 169 wells (Appendix A, Figure A-1, Table A-1). Of these wells, there are 26 active wells, 67 permitted locations, and 76 wells that have been plugged and abandoned. Similar to the one-mile AOR, wells primarily produce from shallow geologic interval (i.e., Tansill-Yates-Seven Rivers), as well as the Bone Spring and Wolfcamp formations. In addition to this, there is one active gas well, within two miles, producing from the Strawn Formation.

There are four wells within two miles of the Titan AGI #4 that penetrate the proposed Siluro-Devonian injection interval (Table 13). All of these wells have been properly plugged and abandoned and are located greater than one mile from the proposed Titan AGI #4 bottom-hole location. These include the South Lea Federal #1 (API: 30-025-23197), Pawnee Deep Unit #1 (API: 30-025-26557), Horse Back #1 (30-025-25354), and the Dogie Draw Federal #1 (API: 30-025-24719). Although the wells were drilled such that they penetrate the proposed injection zone, each was plugged back to produce shallower depth intervals before being plugged and abandoned. The wells are properly cemented through the injection zone and are not anticipated to be negatively affected by the operation of the Titan AGI #4 well. All relevant plugging reports have been included in Appendix A.

Table 13. Wells located within two miles of the Titan AGI #4 well that penetrate the proposed injection interval

API	Well Name	Pool	Status	Latitude (NAD 83)	Longitude (NAD 83)	Total Depth (ft)	Mi. from BHL

6.0 IDENTIFICATION AND REQUIRED NOTIFICATION OF OPERATORS, SUBSURFACE LESSEES, AND SURFACE OWNERS WITHIN THE AREA OF REVIEW

In developing this C-108 application, a detailed review of land records was completed to obtain a listing of all operators, oil and gas mineral leases, and surface owners within a one-mile radius of the proposed AGI well. Appendix B includes the results from that review.

Table B-1 summarizes the surface owners, operators, and lessees in the one-mile area of review. The table is inclusive of all persons that will be provided notice and a complete copy of the C-108 application. Figure B-1 shows the location of the surface owners and active operators, and Figure B-2 shows leaseholders and mineral ownership within one mile of the proposed Titan AGI #4 location.

Upon issuance of an NMOCC hearing date to consider the matter of Northwind's application, all interested parties identified will be provided with written notice of the associated NMOCC hearing and will be provided complete copies of the Form C-108 application. Appendix B includes an example notification letter that will be provided to interested parties, as well as an example public notice that may be utilized by Commission staff or published in local newspapers, as necessary.

7.0 AFFIRMATIVE STATEMENT OF LACK OF HYDRAULIC CONNECTION BETWEEN THE PROPOSED INJECTION ZONE AND KNOWN SOURCES OF DRINKING WATER

As part of the work performed to support this application, a detailed investigation of the structure, stratigraphy, and hydrogeology of the area surrounding the proposed Titan AGI #4 well has been performed. The investigation included the analysis of available geologic data and hydrogeologic data from wells and literature identified in Section 3.0, 4.0, and 5.0 above, including related appendices. Based on this investigation and the analysis of these data, it is clear that there are not open fractures, faults, or other structures which could potentially result in the communication of fluids between the proposed injection zone and any known sources of drinking water or oil/gas production in the vicinity, as described above in Section 4.0 and 5.0 of this application.

I have reviewed this information and affirm that it is correct to the best of my knowledge.

David A. White, P.G. Vice President – Geolex, Inc.® Consultant to Northwind Midstream Partners, LLC

Subsequent Report of Plug and Abandonment

4/8/15---MIRU

4/9/15---RIH w/ WL & Tag in Tbg @ 12,675'

4/10/15---Unset PKR & start to POOH w/ 21/4" Tbg, total of 180 stands so far, PKR depth was 10,436"

4/11/15---Finish POOH w/ Tbg, total of 195 stands (12,347' EOT). RIH w/ gauge ring to 12,630'. Pat @ BLM OK'd to set 5" CIBP @ 12,500' tomorrow

4/14/15---Set 5" CIBP @ 12,500'. RIH Tbg, kept getting behind liner @ 10,510'

4/15/15---Still cannot get inside liner, POOH. RIH w/ mule shoe, tag CIBP @ 12,500'. Spot 40sx H cmt @ 12,500' to CTOC 12,055'

4/16/15---POOH Tbg. RIH w/ 5" model R PKR & set @ 10,574'. RIH WL to perf @ 11,560' -- WL stuck @ 11,500'

4/17/15---Still cannot get WL free. Set off perf charges @ 11,500'

4/20/15---Cut WL & POOH w/ 5000' line. Able to pump down line through Tbg – Sqz 80sx cmt @ 11,500' to CTOC 11,316'. SIW on slight vacuum.

4/21/15---Test below PKR, holding 750#. RIH WL & cannot get past 5,038'. Attempt to POOH w/ PKR, stuck inside 5" liner, worked pipe, still stuck.

4/23/15---Cut Tbg @ 5,044' & POOH. RIH w/ perf sub to 5,044', back off @ 8,250', POOH.

4/27/15---RIH PKR to 4,432', test well, holding 1300#, POOH

4/28/15---RIH w/ 2%" Tbg & corkscrew wireline catch to 8,105', tried retrieving wireline & Tbg parted @ 7,472'. POOH Tbg.

4/29/15---RIH 7" gauge ring to 2,281'. RIH w/ overshot - POOH w/ 77 jts of Tbg and overshot.

4/30/15--- Tag w/ 2% Tbg @ 4,793'

5/1/15---Cannot catch fish, POOH Tbg. RIH w/ new grapple - start pulling on Tbg, parted @ 37'

5/4/15---Cannot catch fish

5/5/15---Cannot catch fish. Got a fisherman on location, finally got onto fish

5/6/15---Backed off 3 its below overshot @ 158', LD Tbg, RIH w/ OS & backed off @ 4505', LD Tbg

5/7/15---Run tally on PH6 Tbg. RIH w/ 137 jts Tbg.

5/8/15---Cannot get past 6,380'. POOH

5/11/15---RIH w/ 6%" impression block to 6,388', wire on block, POOH

5/12/15---RIH w/ wire spear to 6,413', POOH w/ 1000' wire, start to RIH w/ overshot

5/13/15---TD @ 6,691', POOH w/ no fish. RIH w/ wire spear & POOH w/ 3000' wire

5/14/15---RIH w/ overshot to 7,450' - 5D for weather

5/15/15---POOH, no fish. RIH w/ spear, POOH w/ 150'-200' of wire

5/18/15---RIH overshot to 7,485', POOH w/ no fish

5/19/15---RIH w/ impression block to 7,485'

5/20/15---POOH, block shows more wire. RIH w/ Cut Right w/ Diamond Cut inserts to 7,485' -- POOH w/ no fish

5/21/15---RIH w/ wire spear to 7,485', POOH w/ no wire. Start RIH w/ overshot

5/22/15---Worked over fish w/ overshot, POOH w/ no fish

5/26/15---RIH w/ 61/4" concave mill to 7,485', milled 2-3 hrs, POOH w/ Tbg

5/27/15---RIH w/ overshot and Jars to 7,485', cannot get fish, POOH. RIH w/ new grapple

5/28/15---Overshot on fish, jarred on fish @ 7,485' for 5 hrs, made 1'. Jarred and bumped fish, worked up to 7,479'

6/1/15---RIH w/ washpipe to 7,479' & rotated on fish -- made hole down to 7,505', cannot POOH. Jarred on Tbg all day

6/2/15---Freepoint shows 100% free @ 7,411'. Con't jarring - no success

6/3/15---Con't jarring - no success

6/4/15---Backed off below jars @ 7,418'. POOH w/ jars, leaving 1 jt of washpipe w/ bushing & shoe. RIH w/ PKR

6/5/15---Set PKR @ 6,979', test well, holding 1450W. Jim Amos OK to spot 40sx cmt. POOH w/ PKR

6/8/15---RIH w/ perf sub to 6,987' - Spot 40sx cmt @ 6,987' to CTOC 6,767'

6/9/15---Tag @ 6,738'. Perf @ 6,680' (per BLM - Jim Amos). Test well - held 1800# - Spot 40sx cmt @ 6,738' to CTOC 6,518'

6/10/15---Tag @ 6,397'. BLM - Jim Amos - says to go back to procedure. Perf @ 5,300' - Sqz 80sx cmt to 5,100'

6/11/15---Tag @ 5,094'. Pump 150bbl MLF. Spot 200sx cmt @ 4,102' to CTOC 3,533'

6/12/15---Tag @ 3,558'. Spot 90sx cmt @ 3,558' to CTOC 3,320' - Tag @ 3,486'. BLM - Pat ok'd to spot 70sx cmt @ 3,486' to CTOC 3,301'

6/15/15---Tag @ 3,442'. BLM ok'd to spot 45sx cmt @ 3,419' to CTOC 3,300' - Tag @ 3,305'. Spot 45sx cmt @ 1,899' to CTOC 1,780'

6/16/15--- Tag @ 1,713'. Test well - held 1800#. Perf @ 690' - Sqz 85sx cmt to 540'

6/17/15---Tag @ 504'. Perf @ 100' - cannot est rate w/ 1500#. BLM - Pat OK'd to spot cmt to surface - RIH to 155' - pump 80sx cmt to surface inside 10%". RDMO

INSTRUCTIONS

This form is to be filed with the appropriate District Office of the Commission not later than 20 days after the completion of any newly-drilled or despended well. It shall be accompanied by one copy of all electrical and radio-activity logs run on the well and a summary of all special tests conducted, including drill stem tests. All depths reported shall be measured depths. In the case of directionally drilled wells, true vertical depths shall also be reported. For multiple completions, Items 30 through 34 shall be reported for each zone. The form is to be filed in quintuplicate except on state land, where six copies are required. See Buta 1105.

RE: NORTHWIND MIDSTREAM PARTNERS, LLC PROPOSED TITAN AGI #4 (CASE NO. XXXXX)

This letter is to advise you that Northwind Midstream Partners, LLC (Northwind) filed the enclosed C-108 application (Application for Authorization to Inject) on XX/XX/XXXX with the New Mexico Oil Conservation Division (NMOCD) seeking authorization to drill and operate an acid gas injection (AGI) well, the Titan AGI #4 well, at their gas treatment facility in Lea County, New Mexico. The proposed Titan AGI #4 is intended to provide additional operational redundancy for acid gas injection operations and increase the total sour gas treatment capacity at the Titan Treatment Facility.

The proposed well will be drilled from a surface location of approximately 2,529 feet from the north line (FNL) and 617 feet from the west line (FWL), with a deviated wellbore and bottom-hole location approximately 1,532 feet northwest of the surface location in Section 21, Township 26 South, Range 36 East, in Lea County, New Mexico. As proposed, the Titan AGI #4 well will inject waste carbon dioxide and hydrogen sulfide into the Devonian through Fusselman geologic formations from approximately 17,570 feet to 19,130 feet. The maximum allowable surface pressure will not exceed 5,811 psig with a maximum daily injection volume of 28.8 million standard cubic feet (MMSCF) shared between Titan AGI #4 and the currently approved Salt Creek AGI #2.

This application (Case Number XXXXX) has been set for hearing before the New Mexico Oil Conservation Commission at 9:00 a.m. on XX/XX/XXXX, in the Wendell Chino Building at the NMOCD Santa Fe office located at 1220 South St. Francis Drive; Santa Fe, NM 87505. You are not required to attend this hearing, but as an interested party that may be affected by Northwind's application, you may appear and present testimony. Failure to appear at that time and become a party of record will preclude you from challenging the application at a later date.

A party appearing at the hearing is required by Division Rule 19.15.4.13 NMAC to file a Pre-Hearing Statement at least four (4) days in advance of the scheduled hearing, but in no event later than 5:00 p.m. Mountain Time on Thursday preceding the scheduled hearing date. This statement must be filed at the Division's Santa Fe office at the above-specified address and should include the names of the parties and their attorneys; a concise statement of the case; the names of all witnesses the party will call to testify at the hearing; the approximate time the party will need to present its case; and an identification of any procedural matters that need to be resolved prior to the hearing.

If you have any questions concerning this application, you may contact me at Geolex, Inc.®; 500 Marquette Avenue NW, Suite 1350; Albuquerque, New Mexico 87102; (505) 842-8000.

Sincerely, Geolex, Inc.®

David A. White, P.G. Vice President Consultant to Northwind Midstream

ATTACHMENT 2 – SAMPLE PUBLIC NOTICE OF HEARING

Northwind Midstream, LLC; 811 Louisiana St, Suite #2500; Houston, Texas 77022, filed Form C-108 (Application for Authorization to Inject) on XX/XX/2024, with the New Mexico Oil Conservation Division seeking authorization to drill, complete, and operate its proposed acid gas injection (AGI) well, the Titan AGI #4, which is intended to serve as a redundant well option and increase the sour-gas treatment capacity at the Titan Treatment Facility. Titan AGI #4 will be drilled as a deviated well from a surface hole located at approximately 2,529 feet FNL, 617 feet FWL and the bottom hole located approximately 1,532 feet northwest of the surface hole in Section 21, T26S, R36E in Lea County, New Mexico, approximately 7.5 miles southwest of Jal, New Mexico. Northwind seeks authorization to inject up to 28.8 million standard cubic feet (MMSCF) per day of treated acid gas at a maximum pressure of 5,811 psig into the Devonian to Fusselman formations through an open hole completion between approximately 17,570 feet and a total depth of approximately 19,130 feet. The proposed volume of 28.8 MMSCF per day reflects a proposed total capacity shared with the currently approved Salt Creek AGI #2 well.

This application (Case Number XXXXX) has been set for hearing before the New Mexico Oil Conservation Commission at XX:XX a.m. on XX/XX/2024, in the Wendell Chino Building at the New Mexico Oil Conservation Division's Santa Fe office located at 1220 South Saint Francis Drive, Santa Fe, New Mexico 87505. Interested parties that may be affected by Northwind's application may appear and present testimony by filing a Pre-Hearing Statement with the Division's Santa Fe office at the above-specified address at least four days in advance of the scheduled hearing date. Additional information can be obtained from the applicant's agent, Geolex, Inc.®; 500 Marquette Avenue NW; Suite 1350; Albuquerque, New Mexico 87102; (505)842-8000.

APPENDIX C

REQUEST LETTERS FOR PERMISSION TO SAMPLE AND ANALYZE GROUNDWATER AND PROOF OF MAILING

David A. White, P.G.

July 8, 2024

NGL South Ranch, Inc. Attn: Jim Winter 6120 S. Yale Avenue, Suite 1300 Tulsa, OK 74136 VIA CERTIFIED MAIL

RE:

WATER WELL (J00025 POD1) STATUS INQUIRY AND REQUEST FOR GROUNDWATER SAMPLE

To Whom it May Concern:

On behalf of Northwind Midstream Partners, LLC (Northwind), we (Geolex, Inc.®) are contacting you in the hopes that you may provide us with information regarding the current operational status of a water well in which you are documented as the owner of record. If the current state of the well permits, we respectfully request permission to collect and analyze a groundwater sample from this well.

As recorded in the files of the New Mexico Office of the State Engineer, the well file number is J 00025 POD 1 and the well has a recorded location within the NE/4 of the NE/4 of Section 29, Township 26 South, Range 36 East. The approximate geographic coordinates are 32.020951, -103.280668 (NAD83).

Northwind is requesting permission to sample and analyze groundwater from this well in order to provide the New Mexico Oil Conservation Division with required groundwater data in the area of their proposed Class II injection well, the Titan AGI #4. The proposed well is to be located in the SW/4 of the NW/4 in Section 21 of Township 26 South, Range 36 East.

If you have any questions concerning this inquiry or would like to further discuss our request, you may contact me at (505) 842-8000 at Geolex, Inc.®; 500 Marquette Avenue NW, Suite 1350; Albuquerque, New Mexico 87102.

Sincerely, Geolex, Inc.®
