No. 2-86

MEMORANDUM

TO: ALL OPERATORS AND INTERESTED PARTIES,

FROM: R. L. STAMETS, DIRECTOR

SUBJECT: ORDER R-111-A, POTASH-OIL AREA SPECIAL RULES STUDY COMMITTEE

The special rules for drilling wells in the Potash-Oil Area of Eddy and Lea Counties were adopted some thirty years ago. In recent years, potash companies have become more concerned about the potential for leakage of gas from deep high pressure wells into the potash intervals or into the mines directly.

In order to assure that the technical requirements of the regulations meet modern standards, to attempt to address the concerns of the potash industry, and to attempt to set guidelines for Division approval or denial of protested applications, a potash-oil industry study committee will soon be formed.

Any company or person desiring to participate in this committee should notify me of their interest on or before April 30, 1986. Please submit the name, address, and phone number of the appropriate contact person.

POST OFFICE BOX 2088 STATE LAND OFFICE BUILDING SANTA FE, NEW MEXICO 87501 (505) 827-5800

MEMORANDUM

TO: POTASH-OIL AREA SPECIAL RULES STUDY COMMITTEE

FROM: R. L. STAMETS, DIRECTOR

BLL

During the time allotted by Memorandum 2-86, parties listed on the attached list have expressed a desire to serve on our committee. Vic Lyon, New Mexico Oil Conservation Division, Chief Engineer, will chair the committee.

There may have been some conjecture that decisions would be made by a vote count. This may be true of procedural questions, although most such decisions will be made by the chairman. I assure you that decisions on matters of substance will be made by a consensus.

Development in the area in question takes place under provisions of the Oil and Gas Act which preclude oil and gas development if such operations would interfere unduly with the orderly commercial development of potash deposits or unduly reduce the total quantity of such deposits recovered. This has often resulted in a clash of interests as oil and gas operators seek to develop their properties and as potash companies seek to protect their investments, their reserves, and the well-being of miners. Each side has presented strong arguments.

The law does not preclude oil and gas development in this area and we must therefore assume that the intention was to allow wells to be drilled when warranted. The Division on the other hand has no intention of allowing drilling which would threaten the lives of miners or cause undue waste of commercial potash reserves. Our objective in forming this committee is to determine where, when and how both industries may proceed with development of both resources in an efficient manner without endangerment or undue inconvenience to the other. I am convinced this can be done, but it may take some time. We hope this committee can complete its work in about a year.

Note: Mail-out had copy of order R-111-A attached.

I perceive a strong need for a serious and sincere cross-exchange of information and mutual education of how each of the two industries operates and under what conditions. At least one visit to a mine is considered highly desirable. Probably at least one visit to a drilling rig (if one can be found), and/or to producing wells may be helpful. Suggestions are requested for other field trips, lectures, training aids or other means which can be utilized to cross-pollinate the committee members to prepare each of us to understand both sides of the apparent conflict of multiple use of lands and multiple development of resources. I would hope any member of the committee who is unwilling to try to understand the position of the other side would excuse himself from the committee. The mutual education will constitute Phase I of the committee program.

I would suggest that Phase II involve a detailed investigation of existing mining operations and proposed future operations as well as existing oil and gas operations, estimated life, construction and safety features of oil and gas wells.

Phase III should then be the effort to revise Rule R-111 so as to meet the ultimate objective - the embodiment into rules of the means of developing both resources without endangerment of lives or resources and without undue interference, one with the other.

I commend you for volunteering your time and look forward to working with you in this effort. I am confident each of us will benefit personally from the effort and will serve his respective industry well by assuring safe, continued development of our natural resources. We have all accepted a major challenge and I am confident we can meet that challenge.

Our initial meeting will be held in the OCD Conference Room, 2nd floor of the State Land Office Building, Old Santa Fe Trail, Santa Fe, at 9:00 a.m. May 29. A copy of Order No. R-111-A is attached for your information and review. Please read this rule before the meeting.

### POTASH - OIL STUDY COMMITTEE

Agenda for May 29, 1986 Meeting

- 1. Greeting and introductory remarks by Director
- 2. Introduction of members
- 3. Purpose of Rule R-111
- 4. Area covered by Rule R-111
- 5. Secretary's Potash enclave
- 6. Perceived areas of conflict between oil and gas exploration and production versus potash mining.
- 7. Discussion of ways to get on same wave-length
  - a. field trips to learn of each side's operations and conditions
  - b. seminars or guest lecturers to advise of
    - (1) mine safety
    - (2) mining techniques
    - (3) process, timing and areal extent of subsidence following mining operation
    - (4) oil/gas well drilling techniques
    - (5) oil/gas well hazards and safeguards
    - (6) oil/gas well producing life
    - (7) other
- 8. Other items to be discussed
- 9. Set date for next meeting or activity

POST OFFICE BOX 2088 STATE LAND OFFICE BUILDING SANTA FE, NEW MEXICO 87501 (505) 827-5800

### MEMORANDUM

TO: POTASH-OIL STUDY COMMITTEE

FROM: VICTOR T. LYON, CHAIRMAN

Let's try it one more time! Our back-up date of August 21 didn't quite fit either. Our meeting for mutual education is rescheduled for September 25-26 in Santa Fe. Let's all try to make this one fly! If you have a problem with it, please let me know.

Meeting at same time, same place, only the date has changed.

Nic Lyon

GOVERNOR

STATE OF NEW MEXICO ENERGY AND MINERALS DEPARTMENT OIL CONSERVATION DIVISION

POST OFFICE BOX 2088 STATE LAND OFFICE BUILDING SANTA FE, NEW MEXICO 87501 (505) 827-5800

### TO: POTASH-OIL STUDY COMMITTEE

RE: MEETING DATE CHANGE

I have been advised that the selected date for our meeting coincides with the Indian Market, an annual event in Santa Fe. I was aware of that fact and thought it might enhance the meeting with an extra-curricular activity. I was not aware, however, that every room in Santa Fe has been booked for months on that date.

It seems necessary, therefore, to reschedule our meeting to August 21-22, same time, same place. Unless there is a serious conflict, we hope to see you in Santa Fe August 21.

Yours very truly,

ozym

VICTOR T. LYON, Chairman

TONEY ANAYA

GOVERNOR

STATE OF NEW MEXICO ENERGY AND MINERALS DEPARTMENT DIL CONSERVATION DIVISION

July 18, 1986

POST OFFICE BOX 2088 STATE LAND OFFICE BUILDING SANTA FE. NEW MEXICO 87501 (505) 827-5800

POTASH-OIL STUDY COMMITTEE

(address list attached)

A meeting for our mutual education seminar, by consensus of the representatives of the two industries, is hereby called for 9:00 a.m. August 14 in the Land Office Building in Santa Fe. An outline for each industry is attached. If necessary we will continue the session on August 15.

It is hoped that all members will be able to attend. If a serious conflict is caused by this schedule, please let me know and we will try to make other arrangements.

The tentative schedule is to have the potash presentation first, followed by the oil and gas program. We will then try to set a schedule for field trip to mine(s) and drilling well(s).

This is a departure from the schedule we discussed at our initial meeting, primarily because of concern that seminars and field trips would take virtually a full week, which many of us can ill-afford, with the press of business being what it is. August is a busy time in Santa Fe and you are urged to make reservations right away.

We are looking forward to our meeting and will be happy to help anybody in any way we can to make it an enjoyable and educational experience.

Yours very truly,

VICTOR T. LYON, Chairman

VTL/dr

### OUTLINE OF PRESENTATION

### DRILLING AN OIL AND GAS WELL IN THE POTASH-OIL AREA OF NEW MEXICO

### I. PLANNING THE WELL

- A. The subsurface target
  - 1. Southeast New Mexico geological section for oil and gas
  - 2. Lithology of the Salt Section containing the potash beds
- B. Choosing the surface location
  - 1. Potash presence and mining activity in the area
  - 2. Straight or directional hole considerations
- C. Permits, Notices, Regulations, R-111-A Requirements, Contingency Plans

### II. DRILLING THE WELL

- A. Moving in the rig and making ready to drill
- B. Drilling the Surface Hole
  - 1. Well control procedures for surface hole
  - 2. Drilling operations and drilling fluid considerations
  - 3. Selection of casing point
  - 4. Running and cementing the casing string; testing casing upon drilling out
  - 5. Safety considerations and procedures
- C. Drilling the Salt Section\*
- D. Drilling the Intermediate Hole Section\*
- E. Drilling to Total Planned Depth\*
- F. Logging; securing the well and moving out the rig

\*UNDER ITEMS II. C, D, E, a discussion of the same steps as outlined in II. B 1.-5. will be conducted with respect to each section of the hole.

1

### **III. WELL COMPLETION**

- A. Moving in the completion rig; well control procedures
- B. Perforating and testing
- C. Stimulation: acidizing and/or fracturing
- D. Testing the well for production

### IV. PRODUCING THE WELL

- A. Daily well production monitoring (volumes, pressures, etc.)
- B. Workover or restimulation operations
- C. Tubular integrity over time
- D. Disposal of produced water

### V. PLUGGING AND ABANDONMENT

- A. Salvaging the tubulars (tubing and casing)
- B. Cementing procedures and tests
- C. Effectiveness of plugging operation in protecting potash zone
  - 1. Cement plug across potash zone with no casing in hole
  - 2. Cement plug in casing where casing across potash zone cannot be pulled

### VI. ADEQUACY OF RULE R-111-A

- A. Procedural considerations
- B. Technical considerations

### OUTLINE OF POTASH INDUSTRY'S POSITION ON ISSUES RAISED BY MULTIPLE USE OF THE POTASH ENCLAVE

### A. Introduction

- 1. Origin of Potash, deposition characteristics
- 2. How potash is found, mined and processed
- 3. Principal products and uses

### B. Safety of Miners

- 1. Characteristics of hydrogen sulfide and methane gas
- 2. Hazards of hydrogen sulfide and methane gas in underground mines
- 3. History of naturally occurring hydrogen sulfide and methane gas in the Potash Basin
  - a. Minute amounts
  - b. High nitrogen concentrations
- 4. Mine ventilation systems and the current lack of hydrogen sulfide and methane hazards
- C. Hazards Created by Oil and Gas Activities
  - 1. Introduction of hydrogen sulfide and methane gas into layered deposits
    - a. Geology of Potash Basin
    - b. Gas migration
  - 2. Oil and gas accidents
    - a. History of oil and gas accidents
    - b. History of oil and gas accidents in the Potash Basin
  - Washington Ranch gas migration incident
     IMC's experience with grouting at No. 5 shaft
- D. Effect of Hazards from Oil and Gas Activities on Potash Industry
  - 1. Mine Safety and Health standards, attitudes and regulations
  - 2. Mine plans and actual practice
  - 3. Permanency of impact
  - 4. Destruction of mine assets
  - 5. Risk and liability to Potash Industry with benefit to Oil and Gas Industry

### E. Factors that Must be Considered to Address Hazards

- 1. Increased use of state of the art directional drilling technology
- 2. Identification of ore bodies and barren areas
- 3. Subsidence
- 4. Studies on the migration of hydrogen sulfide and methane gas to determine spacing between mining and oil and gas activities
- 5. Increased cooperation between the OCC and BLM
- 6. Identification, control and responsibility for the release of hydrogen sulfide and methane gas
- 7. Increased cooperation between the Industries to ensure that all development activities are performed in a manner that miners are not endangered.
- 8. Adequacy of existing regulations to ensure the safety of miners
- F. Summary

### TC: MEMBERS OF POTASH-OIL STUDY COMMITTEE

FROM: VICTOR T. LYON, CHAIRMAN

SUBJECT: FIELD TRIP TO POTASH MINES

We have scheduled a field trip to observe potash operations, both on the surface and underground. The event is to take place November 13 and 14 beginning at 6:45 a.m. in Carlsbad. An itinerary of the trip is attached. Also attached is a copy of the minutes of our September 25-26 meeting.

We hope you can join us on what promises to be a very exciting and educational experience!

For those coming from out-of-town, you may wish to stay Wednesday night in Carlsbad. It would be very helpful if we could all stay at the same place and the others meet at that place to travel to the mine together.

Mr. Gant earlier offered to make reservations for the group and I have asked that he do that for us. Also the mining group would like a "hard" head-count of the touring group by Monday, November 10 so they can make the necessary arrangements. Please call me before 3:30 p.m. Monday and give me your name or names and I will tell you where we will be staying.

We hope to visit a drilling rig Thursday afternoon and visit the Tech school at Roswell Friday afternoon so we are looking at two full days if all fits together.

See you Thursday morning in Carlsbad.

### MINUTES OF SEPTEMBER 25, 1986 POTASH-OIL STUDY COMMITTEE

The Committee met at 9:00 a.m. September 25 in the OCD Santa Fe office conference room. The Chairman began the meeting by reviewing the objectives of this phase; i.e., to educate each other in our respective areas of operations so that we have a reasonable degree of knowledge and understanding of both industries. It was emphasized that it is not expected to decide any issues at this meeting and that argumentative questions would be discouraged.

The meeting was turned over to Walt Thayer who made some introductory remarks and then turned the stage to Charles High who passed out a bound collection of articles and information on potash mining. A film was shown on potash and mining and then a further presentation giving a rather complete description of potash deposition, evaluation, mining and processing was delivered by Mr. High.

Questions were fielded during the presentation and following the formal presentation a question-answer session followed until the lunch break. All questions were directed for clarification and information to improve understanding of the potash situation. All questions were answered candidly and as completely as time restraints would allow.

Following lunch John Waid made introductory remarks and turned the floor over to Norbert Rempe who described the exploratory techniques for finding oil and gas prospects, the general geology of the area, the bases on which a drilling prospect is chosen and the means of detecting presence of oil and gas while drilling a prospect.

A.J. Deans described step-by-step the procedure of drilling a well, beginning with site preparation, the well plan, moving in the rig and set-up of equipment. The drilling process, setting and cementing of casing, the testing to assure mechanical integrity of each string of casing and means of protecting fresh water, salt and potash zones, as well as shutting off water flows and otherwise preventing flow of any fluids into the well bore were described. The use of mud, its characteristics and purposes and the use of blow-out preventers, how they work and how they operate were covered.

George Buehler gave a thorough description of the well evaluation process from data gathered during drilling, the running of logs, drill-stem tests and other information. The opening of the prospective formation by perforating or open hole techniques and the stimulation of the formation were discussed.

The meeting recessed at 5:10 and re-convened at 9:00 a.m. on the 26th.

Buehler continued his presentation by describing the testing and placing on production, the surface equipment used for a producing property, measurement, on-site treatment and disposition of produced fluids. George also discussed common problems and remedial measures in producing and selling the hydrocarbons and properly disposing of water and other wastes, all of which result in a profit, hopefully.

Questions were answered as fully as possible.

The Chairman commended the group for the presentations, the objectivity of the questions, the candor in answering questions and the over-all cooperative attitude of both groups.

A short discussion for scheduling a field trip resulted in the potash group volunteering to design an appropriate tour and to provide the Chairman the details for approval by the committee.

The meeting adjourned at 11:30 a.m.

Respectfully submitted,

Noffym

VICTOR T. LYON, Chairman

TO:

FROM:

WSH

POTASH-OIL STUDY COMMITTEE

VICTOR T. LYON

Now that we have a new Director of the OCD and have been given the green light to resume our committee activity, it seems appropriate to pick up where we left off.

We started with a short session to organize and chart our course. We then had a long (2 days) session of "skull practice" where each industry attempted to educate the other as to what, how, why, when and where we do what is necessary to conduct our respective businesses. Finally we spent two days in the Carlsbad Area touring two potash mines; a potash refinery (if that is the proper term) where ore is processed for conversion to commercial products; a drilling rig and the Petroleum Technology school at Roswell.

The representatives of the two industries have indicated we have educated ourselves and come to know each other to the extent that we may now proceed to discuss deficiencies of Order R-111-A and to amend the order to make it a better tool to fully protect potash resources, mines and personnel and also explore for and develop oil and gas resources.

I am therefore calling a meeting of our committee for March 19-20, in the OCD Conference Room in Santa Fe beginning at 9:00 a.m. March 19. I ask that each of you again study Order R-111-A and note wherein that order is, or may be, deficient in protecting potash resources, either through failure to consider legitimate concerns, or where it is obsolescent in view of technology developed since the original order was written. We will consider those points and then strive to address them by changes in the order.

If the dates present serious problems to you, let me know and I will look for alternative dates.

February 19, 1987

### MINUTES OIL-POTASH STUDY COMMITTEE MEETING March 19, 1987

The Committee convened at the OCD office in Santa Fe at 9:00 a.m. March 19, 1987. Attendance list is attached. Bill LeMay, the new Director of OCD, was introduced and made brief remarks supporting the continuation and objectives of the Committee.

Charles High, speaking for the potash industry recommended we set a timetable to develop the conclusions and recommended revision to Order No. R-111-A at an early date. There was no dissent to that position.

Upon the Chairman's request for suggestions of deficiencies or areas of possible improvement of the existing order, Mr. High was recognized and presented a list aided by viewgraph projections. In summary these were:

1. Provisions for safety of miners

÷ .

- 2. Selection of suitable drilling locations (outside of commercial potash deposits).
- 3. Oil/gas operator responsibility for gas release into mines.
- 4. Identification of ore-bearing versus barren areas.
- 5. Better well casing programs.
- 6. Usage of directional drilling.
- 7. Uniform rules/regulations for state and federal lands, etc.
- 8. Reporting and enforcement policy regarding mishaps in connection with oil/gas drilling and production in potash area.
- 9. Improved review procedure prior to filing application to drill in potash area.

The oil/gas representatives spoke of the adequacy of casing requirements in the present rules, and a perceived paranoid attitude by the miners about gas from wells. There was active discussion of the respective concerns which aptly demonstrated the need for intense examination of factors leading to disagreement between the two industries.

It was agreed the two industry chairmen would advise the committee chairman by March 27 the names of three individuals from each industry to serve on the work committee. The work

1G 1/3

committee will meet on a day during the week of April 6-10, if at all possible, at a location to be selected other than Santa Fe.

It was requested that the members of the work committee be able to devote a significant amount of time in the next 60 days so as to bring a report to the overall committee as soon as possible. Following acceptance by the study committee, a hearing can be scheduled before the OCC, hopefully before end of summer.

The Chairman was requested to moderate the work committee meetings and it was also suggested the BLM and Minerals & Mining Division be offered representation. These requests will be honored.

The Chairman thanked the members for their attendance and participation. Congratulations were extended to Walt Thayer upon being notified during the meeting of his becoming grandfather to a 6 lb. 15 oz. boy.

The meeting adjourned at 11:00 a.m.

Respectfully submitted,

No Bym

FROM: VICTOR T. LYON

SUBJECT: POTASH-OIL WORK COMMITTEE MEETING

DATE: APRIL 20, 1987

You have been selected by your industry peers to serve on the work committee which has been asked to tailor Order R-111-A <u>et. seq.</u> to today's needs and technology. It has been requested to have the meetings on neutral ground other than Santa Fe, which is convenient only to state and federal employees located there. Consequently, we have selected El Paso to be the site of our first meeting and 9:00 a.m. April 30-May 1 as the time and date. The location is Charlie High's office in MBank Plaza, Corner of Kansas and Mills Streets, downtown El Paso. Nearby hotels are Westin (1-800-228-3000) and Sheraton (915-533-8241).

Potash representatives have suggested a wide range of additional aspects to be considered for inclusion in the amended, or superceding order, including identical, or more compatible, provisions with the federal rules now under revision. I do not intend to dismiss any suggestion out-of-hand that does not conflict with the authority or limitations thereof, of the Energy and Minerals Department.

I am inviting, and hope to have representation from U.S. Bureau of Land Management and State Mining and Minerals Division, at our meetings. We have reduced this committee to working size and we need the input of each member. Please try to be present.

### MEMORANDUM

TO: W. J. LEMAY, DIRECTOR

FROM: V. T. LYON, CHIEF PETROLEUM ENGINEER

SUBJECT: FIRST MEETING OF OIL-POTASH WORK COMMITTEE

The meeting was held in Charley High's office in El Paso at 9:00 a.m. April 30 and May 1. In addition to the industry representatives, Erling Brostuen, Fran Cherry and I, as Chairman, attended. The potash representatives presented a fairly detailed re-draft of Rule R-111-A, as a basis for discussion. It really was a fairly reasonable proposal viewed in comparison to the secretary's order of 1986. Some items were excessively protective of potash in my view.

After preliminary discussion on the potash proposal the oil industry reps asked to be permitted to study it overnight and present comments Friday morning.

In reconvening at 8:00 a.m. Friday morning the oil reps stated they agreed that the secretary's enclave and R-111 should be coextensive to avoid confusion. They also agreed that we should strive to have consistent policies for administering the potash area under state and federal agencies. They are satisfied with R-111 in its present form (with the area changed to coincide with the potash enclave) and do not wish to make other changes.

I requested they present the potash plan to the full oil and gas delegation and make acceptable modifications or an alternative proposal at our next meeting. They agreed to do this and estimated they would be prepared for the second meeting approximately June 1. The meeting adjourned before lunch Friday.

OIL CONSERVATION DIVISION

GARREY CARRUTHERS

POST OFFICE BOX 2088 STATE LAND OFFICE BUILDING SANTA FE, NEW MEXICO 87501 (505) 827-5800

MEMORANDUM

TO: WILLIAM J. LeMAY, DIRECTOR

FROM: VICTOR T. LYON, CHIEF PETROLEUM ENGINEER

SUBJECT: POTASH - OIL & GAS WORK COMMITTEE

The committee convened in Charlie High's law firm conference room in El Paso at 9:00 a.m. July 23, 1987. The attendance list is attached. The chairman reviewed the previous meeting where the potash proposal was discussed and then asked the oil and gas group to present their proposal.

Preliminary to the proposal, Larry Brooks presented a summary of his research on the question of migration in the greater salt section. Larry had reviewed studies in connection with the WIPP site conducted by various agencies. The conclusion was that during the orogeny creating the various traps in the Permian basin some fracturing was induced in the salt permitting some slight migration of oil into the massive salt section where it lies primarily in a dead state. As to permeability of the undisturbed salt and the mud seams there is virtually none. Where mining occurs, stresses induced by removal of salt and potash may create permeability permitting flow of trapped gas. These gases are primarily nitrogen and other inert gases.

The degree of migration from some theoretical leak in an oil or gas well is still in considerable dispute by the two sides. Primary concern seems to arise from high pressure gas rupturing the salt string of casing, inducing fractures in the salt and permitting entry into the mine.

The oil and gas proposal is attached. It contemplates vertical or directional drilling at distances from mining or mined out areas which the oil and gas representatives consider to be safe, which is 200 feet.

It was agreed the potash enclave map should be revised to expand or contract the commercial area based on additional data and that Order R-111 should be adjusted to be coextensive therewith.

IK

The potash people revealed that there are many areas in the commercial potash area indicated on the potash enclave map that are not considered to be commercially mineable and that drilling of wells in such areas would not be protested.

The group agreed to accept that wells can be directionally drilled to formations below the Delaware to displace the bottom-hole location 3/4 mile from the surface locations. The potash people stated that most of the blue areas on the potash map can be reached by such directional wells drilled from noncommercial ore sites.

While the potash people will not agree to identify the "drillable blue" areas in a public record they may be willing to divulge this to BLM and OCD on a confidential basis. Such revelation will probably preclude the establishment of drilling islands and will permit vertical drilling for most oil and gas prospects.

The oil and gas representatives stated the formation of units to protect correlative rights of lessees under undrillable locations would be required. The BLM representative and I agreed our agencies would cooperate by approving such units but pointed out we did not have authority to statutorily unitize such units.

Charlie High stated he would prepare a new draft incorporating the areas of agreement and would mail it to the members during the week of August 10. We would attempt to meet again the week of August 17, again in El Paso. The respective groups will furnish copies to those members of the larger committee and seek their approval and/or comments prior to the meeting.

It looks like we may have a breakthrough which can resolve nearly all questions of drilling if all the parties will stay hitched.

The meeting was recessed Thursday afternoon at about 3:30 for the oil and gas group to adjust their proposal and reconvened at 8:30 Friday morning. The agreement was struck about 10:00 a.m. and the meeting was thereupon adjourned.

### MEMORANDUM

TO: ALL DOCKET MAILING LIST

FROM: WILLIAM J. LEMAY, DIRECTOR

SUBJECT: REVISION OF ORDER NO. R-111 (POTASH AREA)

DATE: NOVEMBER 30, 1987

Attached hereto is an agreement which was executed by members of the Potash-Oil and Gas Work Committee in an attempt to clarify the co-existent rights of lessees within the potash area. This agreement culminates an effort begun on May 1, 1986 in which representatives of the two industries met to gain basic knowledge of each industry and document the concerns of each industry brought about by the operations of the other. Membership in this committee was open to any operator in either industry. At the conclusion of the educational phase, each industry elected three representatives and an alternate as a work committee to develop a mutually agreeable program to permit maximum development of both resources with maximum safety for both industries. The agreement was duly completed and signed November 23, 1987.

The Oil Conservation Commission contemplates a hearing, probably on January 21, 1988 to consider on its own motion the amendment of Order R-111. At this hearing we will entertain comments on:

- 1) the attached agreement which may be pertinent to the amendment of Order R-111;
- 2) the area to be covered by R-111, as amended (note - we are proposing the area be expanded to the BLM "known Potash Leasing Area");
- 3) the casing-cementing requirements of Order R-111-A;
- 4) directional drilling procedures for inclusion in the order;
- 5) a procedure for expanding/contracting the effected area by the pool nomenclature procedure rather than amendment to Order R-111. This would be responsive to changes in the KPLA by BLM.
- 6) Revisions to notice requirements.

### PHILLIPS PETROLEUM COMPANY

ODESSA, TEXAS 79762 4001 PENBROOK

EXPLORATION AND PRODUCTION GROUP Permian Basin Region March 1, 1988

Case 9316: Comments Concerning Proposed Order No. R-111-P

12. 12. MA

State of New Mexico Energy, Minerals and Resources Department Oil Conservation Division P. O. Box 2088 Santa Fe, New Mexico 87504

RECLIVED

MAR 2 1983

OIL CONSERVATION DIVISION

Attn: William J. LeMay, Chairman Commissioner's Hearings

Gentlemen:

Phillips Petroleum Company commends the Oil Conservation Division for holding the meetings, discussions, and hearings to adopt good workable rules governing the development of both potash and oil and gas resources in the potash area of New Mexico. The proposed Order No. R-111-P is a very good step in the elimination of problems between the two industries that has existed for many years. Phillips had a representative attend the hearing, held February 18, 1988, and had a statement to present based on all the material that had been obtained prior to the hearing date. However, after seeing the proposed Order No. R-111-P, which was not distributed prior to the hearing, and listening to the testimony presented, our representative elected to return the proposed R-111-P to Phillips Management for further review. We now submit these written comments and suggestions for your consideration.

The proposed Order No. R-111-P is very well drafted and meets the overall objective of the Division in obtaining a set of workable rules in the potash area. Our first area of concern is in Section III(4) having to do with exceptions to Section IV(3). There was quite a bit of discussion concerning this paragraph at the hearing, held February 18, 1988, and Phillips recommends Section III(4) be retained to allow alternate casing programs that could offer better protection in the salt section. If proper proof is presented requesting an exception to this section, it could eliminate some unnecessary expense to the oil and gas industry. It also provides the Division with authoritative control in this matter.

Section IV(3)(e) - Cementing requirements should be changed to allow alternative cementing programs. With the cements and additives being offered today, twelve hours is plenty of time to allow cement to stand under pressure, before drilling the plug or initiating tests.

Section VII - Location For Wells

Paragraph (1) - This paragraph requires each potash lessee to designate the potash deposits on his lease which would be considered "life-of-mine" (LMR) reserves as described in the agreement of the Potash-Oil and Gas Work Committee dated November 23, 1987. Phillips Petroleum Company requests this paragraph be changed. As was brought out in the hearing on February 18, 1988, the agreement is binding to no one, not even the people who signed it. The agreement, as signed November 23, 1987, is not representative of Phillips Petroleum Company's position in this matter. Phillips believes since the agreement is not binding and the Division cannot adopt the agreement as written, all references to the agreement should be removed from the proposed Order No. R-111-P. The appropriate definitions concerning "life-of-mine" reserves should be written directly in Order No. R-111-P when adopted. There could be too many unanswered questions raised by only referring to the "agreement" in the final Order. Since the agreement is not binding, it could possibly not demand compliance.

Section VII, paragraph (4) - The provisions of this paragraph was also a main topic of discussion at the hearing, held February 18, 1988, and Phillips recommends this paragraph be adopted, after the appropriate definition is provided for in Section VII, Paragraph (1) as discussed above. This would allow for orderly development for oil and gas after notice and hearing, or by mutual agreement between the potash and oil and gas industries. The last sentence in this paragraph should be changed to reflect the removal of references to the "agreement." Again, the agreement is not binding so any reference to the agreement should not be in the final adopted Order No. R-111-P.

Again, Phillips Petroleum Company commends the Oil Conservation Division in their efforts to formulate Order No. R-111-P and we respectfully request our comments and suggested revisions be adopted. If Phillips can be of any further assistance in the matter, please contact me at the letterhead address or telephone (915) 367-1324.

Sincerely.

1sus

RECEIVED

NEW MEXICO OIL CONSERVATION COMMISSION

### DEPARTMENT OF ENERGY AND MINERALS

他们在自己的历史。沿

IN RE: APPLICATION OF THE NEW MEXICO OIL CONSERVATION DIVISION TO REVISE, AMEND, AND RECODIFY ORDER NO. R-111, AS AMENDED

### Case No. 9316

#### COMMENTS OF TEXACO, INC.

At the request of the Commission, Texaco, Inc. submits these comments on the proposed amendments to Rule R-111 in conjunction with the hearing held on the matter on February 18, 1988.

### TEXACO'S POSITION

At the February 18, 1988 Commission hearing, Texaco had its first opportunity to review proposed Order R-111-P. While we believe that the present procedures under Order R-111-A (as amended) are sufficient to prevent waste of hydrocarbon reserves and guard against the undue waste of potash, Texaco generally supports proposed Order R-111-P. However, Texaco strongly opposes the adoption, in whole or in part, of the November 23, 1987 agreement among the members of the Potash-Oil and Cas Work Committee. The reasons for our opposition to the committee agreement are stated below.

By our opposition to the committee agreement, Texaco does not advocate a wholesale abandonment of the effort between the two industries. To the contrary, Texaco commends the efforts of the Division and the committee members. However, Texaco urges that the matter be further considered by the two industries according to concrete procedural and organizational guidelines established by the Commission.

### PROPOSED ORDER R-111-P

While generally supportive of Proposed Order R-111-P, Texaco offers the following comments on these sections of the order:

III(4) The wording "and that no potash resources will be endangered" is new, vague and not defined. This language should be changed or deleted.

VH(1)(a) and (b) The definitions of shallow and deep zones should be redefined. Shallow zone: All formation above the base of the Delaware Mountain group. Deep zone: All formations below the base of the Delaware Mountain group.

VII(1) Exhibit "B" in this referenced section should be deleted. The Exhibit "B", map of the LMR is proposed to be confidential. Affected oil and gas lessees should have the opportunity to view portions of this map affecting their lease along with the data and criteria used to delineate the proposed LMR.

### THE NOVEMBER 23, 1987 AGREEMENT

Texaco believes that the substance of the potash-oil industries work committee agreement and the procedures leading up to its execution are inappropriate. Indeed, the terms of the agreement are violative of the New Mexico Oil and Gas Act, the federal regulations and administrative orders of the Bureau of Land Management, and the federal and state statutes (including

april ap
the Constitution of New Mexico) governing the administration of New Mexico's State Trust Lands. In view of the potential effect on the owners of diverse oil and gas property rights, all of whom are attempted to be treated as a class, the procedures for designating "life of mine reserves" areas (LMR's) where drilling would be prohibited may violate the Fifth and Fourteenth Amendments to the United States Constitution.

The adoption of the work committee agreement as part of proposed Order R-111-P would also be legally deficient for the reason that the agreement is replete with inconsistencies that are directly opposed to many of the main provisions of the order. As much of the testimony of the proponent witnesses irrefutably established, the adoption of the committee agreement is unnecessary for the accomplishment of the purposes of Order R-111-P. Indeed, the provisions of the order and the committee agreement are so at odds that both would be rendered meaningless and wouuld be incapable of being administered.

On an item by item basis, Texaco offers the following criticisms of the November 23, 1987 committee agreement:

## INTRODUCTION

a5

The "Intention" of the agreement contravenes The New Mexico Oil and Gas Act as its general effect is to accord primacy to potash reserves in LMR areas at the expense of oil and gas reserves. To the contrary, the Oil and Gas Act directs the Commission and Division to prohibit <u>any</u> practices which reduce or tend to reduce the total quantity of oil or gas ultimately recovered from any pool while at the same time quarding against operations which "unduly" reduce the total quantity of recoverable potash. (See, 70-2-3[A] and [F], N.M.S.A. [1978].) Nowhere in the Oil and Gas Act is there any authority which allows the development of potash reserves to the exclusion of hydrocarbon reserves. The perpetual prohibition against drilling in the LMR area would do just that. We would also make the following points:

- Creation of LMR's removes more lands from drilling than presently available. Not TRUE
- Creation of "drilling areas" outside of LMR's but within potash area is an illusory consideration: <u>fewer</u> lands will actually be available for permitting for drilling.
- We believe potash mining areas within the LMR are adequately protected by the procedures under R-111-A.
- The potash industry gains no additional safety factor under the letter agreement: drilling distance from mining activities is irrelevant in terms of subsidence and lost potash reserves. Notably, when a potash area is primary-mined, no subsidence occurs. Primary mining also allows the recovery of approximately 75% of the potash resource. Therefore, the loss of potash resources is minimal as compared to the total loss of oil and gas reserves under an absolute drilling ban in the LMR areas.
- I. THE POTASH AREA
  - This section conforms R-111-A area to PLM definition of "Potash Area". This section is appropriate.

- 4 -

## II. DESIGNATION OF MINE RESERVES

A. The LMR designation process is confidential. What would in effect be the condemnation of oil and gas property interests should be subject to adversarial scrutiny (not necessarily <u>public</u> disclosure) by anyone with an affected property interest. Otherwise, the unilateral designation of LMR areas would likely be <u>arbitrary</u> and unsupported by <u>substantial</u> evidence, both of which are unlawful.

Data on which LMR areas would be based is often unreliable: We would note that in OCC Case 9143, a potash operator, in attempting to define its mineable reserves failed to honor a critical core-log which significantly altered the boundary of the barren area. Anyone with an affected property interest must have the opportunity to participate in the creation of an LMR area if they are created at all.

All oil and das property interest owners are not similarly situated. Their interests are diverse. They cannot be treated as a <u>class</u>. Otherwise, due process and equal protection problems arise.

In designating LMP's, there is no requirement that a potash lessee actually own the potash reserves or have a right to mine the reserves subject to the LMR area. This is a highly objectionable provision.

Finally, neither the Oil Conservation Division nor the State Land Commissioner can lawfully delegate their respective authority to a process whereby LMR areas are determined solely by the potash operators and the PLM. By so doing, those public officers would cede their statutory responsibilities to ensure

- 5 -

that hydrocarbon reserves are not wasted and that state trust lands are administered for the optimal benefit of the state's beneficiary institutions. Thus, the very essence of the LMR designation process is unlawful as these public officers are concerned.

III. DRILLING IN THE POTASH AREA

B. As explained above, neither the OCC, State Land Office or PLM can delegate their authority for approving APD's to a process that contravenes the Oil and Gas Act, the Arizona-New Mexico Enabling Act or the Interior Secretarial Order for drilling in potash areas. (See, Section 70-2-3 N.M.S.A. [1978], Enabling Act \$10, Interior Secretarial Order of October 28, 1986.)

1. Buffer Zone

The creation of the buffer zone is dependent upon the process for establishing LNR areas and thus has the same problems.

Also, in view of the geologic characteristics of the potash area and presently available and practicable technology, problems with respect to subsidence, gas migration, mine safety and undue waste of potash are avoidable. Therefore, the offset distances are unnecessary and do not achieve the purported goals of the agreement.

## 6. Abandoned Mine Workings

The abandonment and sealing plan is unnecessary. An oil and gas operator <u>cannot</u> accept responsibility for sealing a mine. As well, it is just as inappropriate to make drilling operations near abandoned mines subject to the unilateral veto of a potash lessee.

- 5 -

The safety certification accomplishes no purpose and is only provocative.

D. We disagree that the need for drilling islands is eliminated. This agreement cannot lawfully abolish drilling areas created by an Interior Secretarial Order.

IV. LOCATION OF WELLS AND NOTICE TO POTASH LESSEES

A. Requirement for unitization is vague, impracticable, accomplishes no apparent purpose and is likely impermissible under State Land Office and BLM Oil and Gas Regulations.

C. This subsection (as does Section IX C of the agreement) attempts to transfer liability by the agreement and is impermissible at law. Moreover, the language purports to make the owner of a lease interest liabile along with those "persons and/or entities involed in the development" whether the leaseholder is actually involved in drilling operations or not.

## SUMMARY

While the order proposed by the Oil Conservation Division is a commendable step in the right direction, it should not be adopted with any reference to the November 23, 1987 Agreement. The agreement while well-intentioned, is legally deficient and is irreconcilable with proposed Order R-111-P.

Because of that importance of this matter, we believe that further deliberations among the Division, the oil industry and potash industry are in order before a final amendment to Order R-111-A is proposed.

大学の言語

Mesa Operating Limited Partnership attended the February 18, 1988, Commission hearing in the above-numbered Case. In response to Director LeMay's invitation of that date, we respectfully request that the following Comment be received into the record of said proceedings.

Mesa Operating Limited Partnership is a Delaware limited partnership formed in August, 1985, as a successor to Mesa Petroleum Co., a Delaware corporation. In 1974, Mesa Petroleum Co. commenced operations on an approximately 5,000 acre prospect situated almost entirely within the Potash Area as established by Order R-111. In the following years, the Mesa Petroleum Co. -- Nash Unit Nos. 1, 2 and 3 wells were completed in the Potash Area as commercial producers of natural gas. Cumulative production from Atoka completions is now 5,307 mmcf, and from Morrow completions 6,630 mmcf.

In 1979, operations began on the Mesa -- Nash No. 7, to be directionally drilled from a surface location in Section 18, T-23-S, R-30-E, to a bottom hole location in Section 7, T-23-S, R-30-E. The well was drilled vertically to 7,000', then kicked out at approximately 18° to a total depth of some 14,000'. The well was plagued by mechanical difficulties from inception. Initial production was shut in after 6 months and never re-established. It is estimated that the directional well exceeded the cost of an equivalent vertical well by \$1.9 million. The ensuing mechanical problems were the significant factor in the failure of production, resulting in the loss of 2,753 mmcf of reserves.

The minimum requirement for economical development of the remaining Nash unit reserves is a program of three development wells: a replacement for the Nash No. 7, and one well each in Section 1, T-23-S, R-29-E and Section 6, T-23-S, R-30-E. Estimated recoverable reserves in Sections 1 and 6 are 2,984 mmcf each, based on average wells.

#### MESA LIMITED PARTNERSHIP

The development program would produce projected revenues as follow, based on an average price of \$2.00/mmcf:

| State of New Mexico<br>Production & severance taxes<br>Royalties, state leases | 1,175,000<br>204,000 |                          |
|--------------------------------------------------------------------------------|----------------------|--------------------------|
|                                                                                | ······               | 1,379,000                |
| Royalties, federal leases<br>Working interest, combined                        |                      | 1,976,000<br>_15,261,000 |
|                                                                                | Total                | \$18,412,000.            |

During the first week of December, 1987, Mesa received the Division's memorandum containing the Potash -- Oil and Gas Work Committee Agreement dated November 23, 1987 (hereafter, "the Agreement"), and advising of the pendency of this proceeding. In reviewing the Agreement, it became apparent that its implementation could foreclose any further opportunity to develop Nash Unit reserves.

The Agreement proposes, of course, that certain areas designated by the potash lessee as life-of-mine-reserves (hereafter, "LMR") would be "permanently protected" from oil and gas operations. An additional buffer of one-quarter mile beyond the LMR would be "permanently protected" from all operations, while a further one-quarter mile extension would be "permanently protected" from operations to depths in excess of 5,000'.

In the event the potash lessee in Mesa's prospective sections filed a LMR designation approximating the contour of measured potash reserves according to the October 1, 1984, Potash Resources Map of the BLM, all of Mesa's projected locations would fall within "permanently protected" areas. As noted above, Mesa's experience with directional wells in this prospect has been distinctly unpleasant.

Under the procedure proposed by the Agreement, Mesa would receive no notice that the LMR designation had been filed. Further, Mesa would have no opportunity to appear and be heard by the jurisdictional agency (the BLM), since no hearing is authorized. Even following the filing of the designation and its final administrative approval, Mesa would not be advised of the result, since the designation is to be treated as a trade secret.

In sum, Mesa faces the permanent condemnation of 8,721 mmcf of proven and probable reserves by <u>ex parte</u> application of the potash lessee, without notice or an opportunity to be heard. Under the Agreement, BLM approval of an LMR would also be binding on the Division.

While we commend the efforts of the Division and of the Work Committee to forge a suitable compromise, Mesa cannot support what could, in the case of the Nash unit, amount to a complete abrogation of the Commission's authority to prevent waste of petroleum resources. Mesa stands in opposition to any proposal that the Agreement as such be endorsed or adopted by the Division. It was with palpable relief, then, that we received proposed Order R-111-P and Chief Engineer Lyon's testimony of February 18, 1988. Time and again during direct and cross-examination, Mr. Lyon affirmed that the Commission will not delegate its discretion to decide permit applications according to their merits and on the basis of an evidentiary hearing. In contrast to the Agreement, the proposed order preserves the discretion of the Division to balance the interests of both potash and petroleum lessees, as developed in an adversarial proceeding, and to fashion an order consistent with the public interest. Mesa, then, finds the proposed order worthy of its full support.

It nevertheless appears that certain portions of the proposed order would benefit from clarification, consistent with the policy objectives urged by Mr. Lyon. For example, paragraph VII (1) of the proposed order states in regard to LMR lands that drilling applications "will not be approved, except as provided in (3) hereinbelow." The ensuing paragraph (3) is addressed to notice of hearing rather than approval of drilling applications. The approval provision is contained in part (4). Accordingly, part VII (1) should be revised so as to refer to part (4), rather than part (3).

In two instances, the proposed order purports to incorporate by reference certain parts of the Agreement. In paragraph VII (1), the definition and designation procedure for LMR's is adopted by reference. In paragraph VII (4) of the proposed order, that portion of the Agreement is adopted which provides guidelines for approval of applications to drill at locations outside the LMR and its buffer.

On cross-examination by Mr. High, Mr. Lyon testified that it was not intended that the entire Agreement be adopted. Obviously, then, only those portions of the Agreement which are germane to the incorporating provision of the proposed order should be included. With reference to LMR's, the appropriate provisions of the Agreement are those included as sub-sections "A" through "D" under the heading "II. Designation of Mine Reserves."

With reference to permit applications outside the LMR and its associated buffer, the relevant portions of the Agreement are set forth as sub-section "B" under the heading "III. Drilling in the Potash Area". Paragraph B(1) deals with locations inside the LMR and its buffers, and is thus not relevant to the proposed order. Paragraphs B(2) through B(4) cover the subject matter referred to in the proposed order, and are therefore to be included.

Paragraphs B(5) and B(6) should not be included, because they contradict the announced policy of the proposed order. Paragraph B(5) is an absolute prohibition of operations with a certain distance of an open mine. The policy of the proposed order is to consider all applications on a permit-by-permit basis, and an absolute prohibition is utterly inconsistent with that policy.

Paragraph B(6) prohibits operations near an abandoned mine unless approved pursuant to sub-section C. That sub-section vests final approval authority in "the sole discretion of the affected potash lessees." In light of the avowed policy of the Division to refuse to delegate its jurisdiction, this -(, -

petied.1

to dallin

NO

way.

provision has no place in the proposed order. Only paragraphs B(2) through B(4) of Article III of the Agreement, then, are to be incorporated. A clarification of paragraph B(2), however, is in order.

Paragraph B(2) of Article III of the Agreement refers to permit applications for locations outside the LMR and its buffer, but within one-half mile of the LMR. It again contains an absolute prohibition of certain operations, in this case those extending below 5,000<sup>+</sup>. For the reasons noted above, this prohibition is contrary to the policy of the Division. Furthermore, the distinction between shallow and deep operations was promulgated by the Division in relation to casing requirements, and was never intended to be an independent basis for denial of an application. The depth restriction contained in paragraph B(2) should therefore be deleted.

Finally, the third sentence of paragraph VII (4) of the proposed order now reads as follows: "The Division will first ascertain from the BLM that the location is not within the LMR area." This implies that the application is not to be further considered if the location is within the LMR area. A more appropriate wording would be that the Division first ascertain "whether the location is within the LMR area." This retains the meaning of the cited provision, but avoids the misleading implication. "we mean it that

The text of the proposed order as presented in this proceeding is attached hereto for reference, reflecting each of the revisions suggested above. Insertions and deletions by this author are indicated in the conventional manner. The appropriate exhibits are also attached.

The Commission is charged by statute with the responsibility of providing for the economical conservation and development of not only the State's potash resources, but its petroleum resources as well. Mesa does not believe that the Commission's dual objectives will be well-served by abrogating its decisional authority to the potash lessee or the BLM. Those ends will be most likely met through a process which allows both of the industries to fully express their respective views, and which allows the Commission to exercise its considerable discretion in favor of the public, as well as private, interests. Accordingly, Mesa urges the adoption of proposed Order R-111-P.

Respectfully submitted,

MESA OPERATING LIMITED PARTNERSHIP

5)

OIL CONSERVATION DIVISION

Dear Mr. LeMay:

William J. LeMay, Chairman

310 Old Santa Fe Trail Santa Fe. New Mexico 87504

New Mexico Oil Conservation Commission

State Land Office Building, Room 206

Exxon supports the positive changes contained in proposed New Mexico Oil Conservation Division Order R-111-P. This proposal provides an opportunity for coexistent petroleum and potash reserve development, while minimizing Order R-111-A provisions which now unnecessarily restrict and burden both industries. From our perspective, eliminating the generally fruitless arbitration process and allowing more routine permitting of wells outside buffer zones are major improvements. We commend Mr. Lyon for this proposal and his very active attempt to address the sometimes divergent areas of concern expressed by representatives of each industry. Our comments on the specific issues surrounding adoption of Order R-111-P follow.

## Opportunity to Drill Within LMR and Buffer Zones

We strongly agree that the NMOCC should not delegate its authority under N.M. Stat. Ann. § 70-2-12(B)(17) (1987 Repl.)

to regulate and, where necessary, prohibit drilling or producing operations for oil or gas within any area containing commercial deposits of potash where the operations would have the effect unduly to reduce the total quantity of the commercial deposits of potash which may reasonably be recovered in commercial quantities or where the operations would interfere unduly with the orderly commercial development of the potash deposits.

Under this statute, to prohibit drilling requires evidence that drilling would (1) unduly reduce potash recovery, or (2) unduly interfere with orderly potash development. Exxon presented evidence at the captioned hearing that a blanket prohibition of drilling in Life of Mine Reserve (LMR) and buffer zone areas would significantly and adversely affect development of oil and gas reserves, however, no evidence was presented to the Commission to support the proposition that a blanket prohibition of drilling in LMR and buffer zone areas furthers the above statutory aims. If adopted in R-III, a blanket prohibition against drilling within the LMR and buffer zone areas may well be an improper (and illegal) delegation to the potash lessees of the authority granted to the Commission by the legislature to make the determinations required by statute.

## Knowledge of LMR Boundaries

Although the location of LMR areas and buffer zones surrounding those areas would have a significant effect on an operator's decision on lease acquisition and development, no adequate mechanism exists in the proposed rule for an operator to gain knowledge of the location of LMR boundaries. Exxon suggests that a mechanism for a confidential disclosure to affected parties be incorporated into R-111-P.

## Exclusion of "Statement of Agreement" from R-111-P

We recommend that applicable portions of the November 23, 1987 "Statement of Agreement" be incorporated into R-111-P, rather than attaching the "Statement" as an exhibit to R-111-P. Such an attachment could cause problems in the future, because it seems logical for a court to assume that something attached as an exhibit to an order is incorporated in the order.

For example, a provision such as the imposition of liability contained in the "Statement" paragraphs IV(C) and IX(C) is not needed or appropriate in NMOCD regulations, and was wisely omitted from R-111-P. Exxon fully supports this deletion. However, including the "Statement" as an exhibit may falsely indicate that the same provision had been incorporated by reference. In fact certain items, such as the new 20-day objection period, are addressed only in the "Statement" is to be part of the revised order. Since only portions of "Statement" parts II, III(B)(1-6) and IV(B) are used in R-111-P, exclusion of the entire "Statement" from the Order would not add significantly to the length of R-111-P.

## Requirement for Pressure Relief Device on Casing

Part IV(3)(H) of proposed Order R-111-P as written could potentially take control of the well away from the drilling contractor/operator during difficult well control situations and could prevent operations to bring the well under control. Once the line from the relief valve is open, the well is in an uncontrolled state. The rule states that a relief valve should be set to 80% of the burst rating of new casing and 60% for used casing but does not specify the basis for the rating. Also, the last sentence of the rule states that the intermediate and production casing strings are cemented to surface which does not conform with Item IV (4) and IV (5) in the proposed order.

We suggest that Item IV (3) (h) be changed as follows: "Before drilling the plug a drilling spool installed below the bottom blowout preventer or the wellhead casing outlet shall be equipped with a rupture disc or other automatic pressure-relief device set at 80% of the API rated burst pressure of new casing or 60% of the API rated burst pressure of used casing. The disc or relief device should be connected to the rig choke manifold system so that any flow can be controlled away from the rig. The disc or relief device shall remain installed as long as drilling activities continue in the well until the intermediate or production (asing is run and cemented".

## William J. LeMay, Chairman

Thank you for the opportunity to provide these comments. If you or your staff wish to discuss any of the above points, please call Bill Duncan at (915) 686-4105.

Sincerely, Richard D. Godd

Re: Revision of Order No. R-111 Oil Potash Agreement

Dear Mr. LeMay:

In accordance with your decision to accept written comments regarding the proposed Rule R-111-P, we are re-submitting our comments of February 12, 1988.

In addition, we are concerned about attaching the Statement of Agreement as Exhibit B. The differences in content could be the basis for possible future conflict.

Sincerely,

El Bulk-

Re: Revision of Order No. R-111 Oil Potash Agreement

Dear Mr. LeMay:

We have reviewed the agreement submitted on behalf of the Potash and Oil and Gas Industries. At this time we would like to endorse the general idea of the plan. However, we have several concerns which we would like to bring to your attention.

Section II - Designation of Mine Reserves Paragraph A. Life-of-Mine Reserves

In the course of designating the Life-of-mine reserves, the Oil and Gas Industry should be notified if these reserves are to extend beyond what is now considered to be the known potash leasing areas. If there are areas of conflict, negotiation should be undertaken to resolve the reservation of disputed areas.

Paragraph C. Revision to LMR's

The Potash Industry should be charged with notifying offset oil and gas lessees of revisions to their original LMR's. If there is conflict between the revisions and existing leases, resolution should be negotiated so as to minimize adverse development to both industries.

Section III - Drilling in the Potash Area Paragraph B-1. LMR and Buffer zone.

We suggest that the buffer zone areas be clarified. Possibly there could be more than one classification depending on the proximity to active mining areas, abandoned areas and possible future mining areas. We suggest that time frames for possible development and economics might be considered. February 12, 1988 William J. LeMay Page two

## Paragraph B-2. Outside Buffer Zone but Within 1/2 Mile.

We would like justification for the depth limitations in this area. A prudent oil and gas operator, who wishes to develop their leases, should not object to circulating cement and using other state of the art methods to ensure that gas migration from deeper zones through the well bore does not occur. It is unlikely that gas would migrate naturally through the rock. Directional drilling to the deeper zones of interest, approximately 7500+, would in many cases not be cost effective. It is also not a "simple" task.

## Paragraph B-6. Abandoned Mine Workings

The Potash Industry should be responsible for a safety plan and the sealing off of abandoned mine areas. This is their area of expertise. The Oil and Gas Industry should be charged with working with the Potash Industry. If a mine operator would ordinarily be required to seal off an abandoned area they should be responsible for the normal expenses incurred.

## Section IV. Location of Wells and Notice to Potash Lessee Paragraph C.

Failure of a potash leaseholder to object to a location should release the oil and gas operator from at least some liability. The Potash Industry should be charged with being responsible for their action or inaction.

The Potash Industry should monitor the level of gases in their mines so that if there is an intrusion of foreign gases or liquids the change can be accurately determined. Monitoring history would probably also be useful in determining the source of the intrusion. The Oil and Gas Industry should not automatically be held responsible. The offset oil and gas operators should be charged with working with the Potash Industry to determine the source of any foreign intrusion and resolution of the problem.

## Section VIII. Filing of Well Surveys

The last statement should be expanded. The words "all encounters" need to be clarified. Does the word "all" literally mean all. We suggest that threshold levels be set. Hydrocarbon and hydrogen sulfide sensors can be installed during drilling operations and on surface facilities.

# Section IX. Additional Safety Requirements and Emergency Action Paragraph C.

Failure of the Potash Industry or the Oil Conservation Commission to take action when they are notified, by an operator, should relieve the Oil and Gas Industry of at least some of the liability for damages caused by oil and gas activities. The Oil and Gas Industry, February 12, 1988 William J. LeMay Page three

and a second product of

because of the nature of the potash activities, depends on the Potash Industry for their input and information. Their input is necessary to help ensure that oil and gas activities do not adversely affect potash activities.

We appreciate the opportunity to comment on this agreement. ARCO offers continuing support and cooperation in achieving a mutually satisfactory agreement.

1

Sincerely,

ElBush

Potash-Oil Industry Agreement Re: Docket No. 6-88 Case 9316

Dear Mr. LeMay:

This letter is submitted on behalf of the Carlsbad Potash Industry ("Potash Industry") in further opposition to the adoption of Proposed Order R-111-P in the above-captioned matter. We would appreciate you including this letter as part of the record in the case.

Our opposition to Proposed Order R-111-A currently as First, the structure of drafted is two-fold. the Proposed Order, which consists of the Order and two exhibits, one of which is the Potash-Oil Industry Agreement, creates unavoidable inconsistencies and, for this reason, will create more questions than it will answer. For example, the text of the Order defines the "Potash Area" as being the same as the U.S. Bureau of Land and Management's ("BLM") "Known Potash Leasing Area". Exhibit B to the Order, however, defines the Potash Area by reference to the "potash area" designated by the Secretary of the Department of Interior in Section V of the Order dated October 28, 1986 and published at 51 Fed. Reg. 39426. It is unclear to us which of these definitions would be controlling since they are both part of the total "Order".

Mr. William J. LeMay March 3, 1988 Page 2

This same confusion exists in several other instances, including the following:

- 1. The provisions of Article VII, entitled "Location for Wells" is based upon but nevertheless different from the language used in Article II of Exhibit B; and
- The notice requirements in Article VII, §2 of the Order are different from those set forth in Article IV, §B of Exhibit B.

In addition to these inconsistencies, it is not clear from the Proposed Order what effect other provisions in Exhibit B would have if the Proposed Order is adopted in its current form. For example, the following provisions in Exhibit B are not even referred to in the text of the Proposed Order but, we assume, would be given effect, since they are part of Exhibit B:

- 1. Article I, \$B, definition of "potash"; no definition
- 2. Article II, §C, amendment of LMR's; Quound
- 3. Article III, §B, LMR's and buffer zones;  $c_{\ell} \sim c'$
- 4. Article II, §C, drilling in the vacinity of abandoned mine workings that are connected to an existing mine; Control
- 5. Article IV, §C, failure of a potash lessee to object to a well location; not needed
- 6. Article IX, \$A, requiring the use of appropriate technology and observance of the prudent operator standard to reduce the hazards of drilling activities; and *not needed*
- 7. Article IX, §C, concerning the control and response to safety hazards.

The foregoing confusion, we believe, is unavoidable if the Order finally issued by the OCC in this case is based upon a rewriting of existing Order R-111-A, as amended. Perhaps some of this could be avoided by the inclusion of a statement saying that the entire contents of Exhibit B are incorporated by reference into the Order and that one or the other is controlling in the event of a conflict. The preferred solution, however, in our opinion, would be the adoption of an order Mr. William J. LeMay March 3, 1988 Page 3

no.

Χ¢

that follows very closely the contents of Exhibit B instead of Order R-111-A. Notwithstanding the limited opposition at the hearing, it is clear beyond question that the parties to Exhibit B represent almost 100% of the affected potash lessees and a large percentage of the affected oil and gas lessees. To give effect to that Agreement, therefore, would be consistent with the expectations of both Industries.

Our second basis for objecting to the Proposed Order is Industries, as you know, is the assurance to the Potash Industry that no wells will be drilled in its LMR's. Without this no agreement would have been possible. In exchange, the Potash Industry was, and is, willing to withhold objections to oil and gas activities in areas of lower provided certain safety standard must be encompt to conserve valuable potash reserves, but to avoid the creation of a hazardous condition to underground miners.

> We do not believe that Article III, §4, of the Proposed Order is consistent with these concepts because it would allow the waiver of the R-111-A casing requirements in areas in close proximity to the LMR's. Accordingly, we strongly recommend that this Section be deleted or redrafted to make clear that the casing requirements as set forth in Exhibit B will be observed.

> We are likewise opposed to the language used in Article VII, §4 since it seems to say that wells will be allowed in the LMR's. This is a critical issue to us for the reasons stated above. To correct this, and to give effect to the Agreement between the Industries, we urge that all of Section 4 be deleted except for the first two sentences and the following substituted:

"Applications for permits to drill will be approved" or denied in accordance with the provision of Exhibit B."

and an end of the second of

While these revisions would remove our major objections to the Proposed Order, we still believe the best solution is to draft a revised proposed order based upon Exhibit B and parties. further comment by interested publish it for Alternatively, we urge that Articles III, §4, and Article VI, §4 be revised as suggested so that the fundamental concepts underlying Exhibit B are preserved.

Mr. William J. LeMay March 3, 1988 Page 4

We appreciate the opportunity to submit these comments and want to thank you and your staff for the time and effort spent over the last 18 months in arriving at a workable agreement.

Sincerely,

KEMP, SMLTH, DUNCAN & HAMMOND By: Charles C. AHigh

MAR 4 1988

## STATE OF NEW MEXICO OIL CONSERVATION COMMISSION

AL LOCALINA.

IN THE MATTER OF THE HEARING CALLED BY THE OIL CONSERVATION DIVISION FOR THE PURPOSE OF CONSIDERING COMMISSION ORDER NO. R-111

CASE NO. 9316

## ADDITIONAL COMMENTS FOR THE RECORD

Comes Now William R. Humphries, Commissioner of Public Lands for the State of New Mexico (Commissioner), by and through the undersigned counsel, pursuant to the direction of the Commission submits the following additional comments for the record:

As previously entered into the record, the Agreement 1. executed by the Potash-Oil and Gas Study Committee, gives the Bureau of Land Management (BLM) the authority to designate life of mine reserves (LMR's) without regard to whether the lease covers state or federal land. The inference of such authority on the part of the BLM, totally infringes on the jurisdiction of the Commissioner of Public Land. Moreover, because of language in the agreement. attempts to secure reserve data, buffer zones and legal locations may be thwarted if such information is exclusively within the control of the BLM. The State Land Office would need this information in order to ensure that state lands are treated equitably with federal lands.

2. In conjunction with the points raised in No. 1 above, the requisite approval by the BLM for all well locations further infringes on the legal authority of the Commissioner. Thus, federal land may be favored over state land as well locations are approved.

stated in the Commissioner's original Entry of 3. As Appearance, the BLM will determine the unitization of oil and gas leases in areas designated as a LMR, even though the State Land Office must first consent to the unitization of any state lease. This situation creates the possibility of forced unitizations as a method of preventing lease expirations and elimination of development obligations. This forced unitization would tie up state acreage and because of the federal practice of designating participating and nonparticipating areas it could also conceivably deprive the State of royalty and tax revenues. This entire focus is inconsistent with the primary purpose of units being formed on the criteria of common geological characteristics.

4. As a means of allowing maximum and timely development of state lands within the potash area it is recommended that the concept of drilling islands be adopted. A drilling island would be a parcel which would be dedicated to oil and gas drilling operations. The island would consist of 40 acres in either one or two parcels. A single parcel should be centrally located so that all parts of the section are accessible from a central location. Alterna-

tives would be two 20-acre islands located one each per 320 acre tract. This 20-acre proposal would allow for greater flexibility. Total acreage withdrawn from potash mining would be 40 acres/640 acres, or a 6% withdrawal. If an island tested dry, exploration rights would revert back to the potash interest.

5. Directional surveys should be are required in the potash zone to locate well bores accurately. This practice would promote safety of property and lives. It would also allow maximum extraction of potash. Paralleling this operation, mining interests should be required to provide accurate maps of their subsurface operations.

6. Under the present R-111, casing programs are specified. These programs should be reviewed and redesigned if they are inadequate. The load bearing capacity of a drilling island would probably provide adequate protection for the cemented well bore from torsion, shear and mining accidents.

7. In all cases, mine safety should be an important consideration and there is a strong likelihood that new rules would be required. However, with careful attention, it is our belief that both industries can coexist and operate profitably in the same area. 8. In light of the percentage of state lands, in the potash area, approximately 16 percent, it is questioned why the Land Office was not asked to participate on the Potash Committee.

ATTN: Mr. William J. Lemay, Director

RE: Case 9316 - Hearing - February 18, 1988 Proposed OCD Order No. R-111-P Potash Area, Eddy & Lea County, New Mexico

Dear Sir:

Representatives of The Louisiana Land and Exploration Company ("LL&E") attended the February 18, 1988 hearing on the captioned matter. LL&E offers the following comments, pursuant to the OCD's invitation at the hearing for additional public comments:

1.

We preface our comments by advising the LL&E has more than general oil and gas industry concern over the restriction or withdrawal of public lands from oil and gas drilling and development operations. LL&E or Inexco Oil Company ("Inexco"), its wholly-owned subsidiary acquired in 1986, already holds oil and gas leases in three prospect areas involving acreage within the Known Potash Leasing Area ("KPLA"), in addition to interests in productive oil and gas leases in Bilbrey Field lying both within and outside the KPLA. We have other current oil and gas leads in various stages of prospect evaluation and have been considering geophysical evaluation of the general potash leasing area on an ongoing basis. Our plans will obviously be directly impacted by proposed Order No. R-111-P.

2.

LL&E opposes general principles of the Potash-Oil and Gas Study Committee's Agreement dated November 23, 1987 to the effect that (a) it imposes a compromise all-or-nothing line between areas where oil and gas drilling is permitted and not permitted, (b) it imposes inflexible and excessive buffer zones in which such drilling is not permitted, (c) it provides no procedure to consider each drilling

Mr. William J. Lemay March 8, 1988 Page 2

proposal on a case-by case basis, regardless of the merits or lack of substantial interference with present or potential potash operations, and (d) it precludes such drilling on a large amount of acreage designated as commerical by the potash industry which is not currently under lease for potash nor is reasonably expected to be offered for lease in the near future. We are not impressed by the potash industry's assertion that approximately 25% of the present "commercial" potash area will soon be removed from KPLA status; no information as to location within the larger potash area is available and apparently little consideration has been given to the overlap effect of large buffer areas to rule out drilling for oil and gas in enclave non-commercial areas, whether before or after such reduction is given effect.

We support the OCD's procedure in proposed Order No. R-111-P (VII, (1) and (4)) that applications for oil and gas drilling locations on State of New Mexico acreage outside the "life-of-mine reserves" ("LMR") area would be approved by the OCD, and that applications for such locations within the LMR area would be considered on an ad hoc basis, by notice and hearing or by mutual agreement between lessor and lessees of both potash and oil and gas interests. We agree with Mr. Victor Lyon's testimony that the OCD cannot compromise or delegate any mandates of state law in considering drilling applications, and that the November 23, 1987 agreement is not legally binding on any parties. We therefore strongly object to references in the proposal order to the November 23, 1987 agreement and its incorporation by reference as Exhibit "B" of the proposed order. Removal of such references would, of course, require that any concepts such as LMR and buffer zones (if any) borrowed from said November 23, 1987 agreement be defined in the proposed order.

We feel that it is necessary to go beyond the foregoing objection, which was made at the hearing, to be sure that the November 23, 1987 agreement is not in fact used as an "unofficial" guideline by the OCD despite omission from the text of the proposal order. In our view, the proposed order (III, (2)), following the current order, very succinctly states the governing general principle that neither potash nor oil and gas operations will be allowed to "unreasonably interfere" with development of the other resource. The entire proposed order should be consistent with this balancing-of-interests principle, imposing the burden of proof upon the opponent of any proposed drilling operations, to show cause why the proposed operations should not be permitted, and the OCD should approve the permit application if, in its opinion on a case-by-case basis, such burden of proof has Mr. William J. Lemay March 8, 1988 Page 3

not been met. We concur in the comment made by one party at the hearing that the reference in the proposed order (III, (4)) "that no potash resources will be endangered" appears not to be supported nor defined by law, and in our view directly conflicts with the aforesaid general principle encouraging multiple use.

We do concede that certain confidentially provisions would be appropriate to protect against public disclosure of certain potash (and oil and gas) information that might be submitted in OCD hearings in which drilling applications are challenged by potash interests.

3.

Mr. Ernie Szabo pointed out at the hearing that there appeared to be no provision in the proposed order addressing possible future changes in the LMR boundary, either expanding or contracting the LMR area. Another party at the hearing commented that there appears to be no mechanism in the proposed order for eventual removal of acreage from the LMR area which has been demonstrated to be non-commercial, e.g., by depletion due to production of potash or by additional coring or other data. We suggest that the OCD consider the feasibility of covering these related matters in the proposed order.

4.

If the concept of a buffer zone around the LMR area is employed, it should be defined in the proposed order itself and should be greatly narrowed in terms of distance. Our application of a buffer zone as set out in the November 23, 1987 agreement (differing as to depth) to the map of the potash area provided at the hearing leads us to conclude, as noted above, that it would in practice overlap so as even totally to exclude from oil and gas drilling many or most enclave areas of non-commercial potash deposits. Also, its breadth would render impossible or impractical the drilling of directional wells to reach oil and gas objectives. It is LL&E's position that there is no scientific justification for a buffer zone employing offset drilling distances in the range of a mile or half mile (depending on objective depth of the proposed oil and gas well), nor for a buffer zone employing such drastic differences in offset distance based on such objective depth. We recommend that the OCD carefully review evidence submitted on these points at the recent hearing and on previous occasions, and evidence otherwise available.

Mr. William J. Lemay March 8, 1988 Page 4

- 11

5.

At the hearing Exxon, and perhaps other participants, raised the issue of whether the current system is reasonable in that it makes no restriction on leasing State of New Mexico acreage for oil and gas, but on the other hand does not specify drilling restrictions on the acreage, in whole or part, at the time it is offered for lease. While LL&E does not support broad withdrawal of acreage from oil and gas leasing, as so often is the case with Federal lands in various parts of the nation, there should be a systematic procedure to advise potential bidders whether part or all of tracts offered for lease cannot be drilled from a surface location either thereon or within a certain distance therefrom. The current system appears to contemplate an all-or-nothing gamble as to drilling rights at a point in time after, rather than before, significant capital and evaluation investment in oil and gas leases has been made.

\* \* \* \* \* \*

LL&E appreciates the opportunity to comment upon proposed Order No. R-111-P and trust that these comments will be favorably acted upon. We apologize for the delay in submitting these comments. At the February 18, 1988 hearing we were not given a precise deadline for additional comments, but only a general reference to two weeks with no indication that the timing was critical. In any event, we want you to have our input whether or not it becomes part of the official record of the case.

We also want to concur in the expression of recognition and support for the diligent effort made by the OCD and by the Potash-Oil and Gas Study Committee on this matter. In our view, the recent inter-industry communication and education has been extremely important and should continue regardless of the nature of any changes made by the OCD to the proposed order as a result of the February 18, 1988 public hearing and related public comments.

If we can be of any further assistance to the OCD in this matter, please call upon us.

Sincerely,

Paul F. Nielsen Staff Landman

## BEFORE THE

#### NEW MEXICO OIL CONSERVATION COMMISSION

## DEPARTMENT OF ENERGY AND MINERALS 1666

THE COME DO A DAY LAND

IN RE: APPLICATION OF THE NEW MEXICO OIL CONSERVATION DIVISION TO REVISE, AMEND, AND RECODIFY ORDER NO. R-111, AS AMENDED

Case No. 9316

## COMMENTS OF TEXACO, INC.

At the request of the Commission, Texaco, Inc. submits these comments on the proposed amendments to Rule R-111 in conjunction with the hearing held on the matter on February 18, 1988.

## TEXACO'S POSITION

At the February 18, 1988 Commission hearing, Texaco had its first opportunity to review proposed Order R-111-P. While we believe that the present procedures under Order R-111-A (as amended) are sufficient to prevent waste of hydrocarbon reserves and guard against the undue waste of potash, Texaco generally supports proposed Order R-111-P. However, Texaco strongly opposes the adoption, in whole or in part, of the November 23, 1987 agreement among the members of the Potash-Oil and Gas Work Committee. The reasons for our opposition to the committee agreement are stated below.

By our opposition to the committee agreement, Texaco does not advocate a wholesale abandonment of the effort between the two industries. To the contrary, Texaco commends the efforts of the Division and the committee members. However, Texaco urges

- 1 -

that the matter be further considered by the two industries according to concrete procedural and organizational guidelines established by the Commission.

## PROPOSED ORDER R-111-P

While generally supportive of Proposed Order R-111-P, Texaco offers the following comments on these sections of the order:

III(4) The wording "and that no potash resources will be endangered" is new, vague and not defined. This language should be changed or deleted.

VI(1)(a) and (b) The definitions of shallow and deep zones should be redefined. Shallow zone: All formation above the base of the Delaware Mountain group. Deep zone: All formations below the base of the Delaware Mountain group.

VII(1) Exhibit "B" in this referenced section should be deleted. The Exhibit "B", map of the LMR is proposed to be confidential. Affected oil and gas lessees should have the opportunity to view portions of this map affecting their lease along with the data and criteria used to delineate the proposed LMR.

## THE NOVEMBER 23, 1987 AGREEMENT

Texaco believes that the substance of the potash-oil industries work committee agreement and the procedures leading up to its execution are inappropriate. Indeed, the terms of the agreement are violative of the New Mexico Oil and Gas Act, the federal regulations and administrative orders of the Bureau of Land Management, and the federal and state statutes (including

- 2 -

the Constitution of New Mexico) governing the administration of New Mexico's State Trust Lands. In view of the potential effect on the owners of diverse oil and gas property rights, all of whom are attempted to be treated as a class, the procedures for designating "life of mine reserves" areas (LMR's) where drilling would be prohibited may violate the Fifth and Fourteenth Amendments to the United States Constitution.

The adoption of the work committee agreement as part of proposed Order R-111-P would also be legally deficient for the reason that the agreement is replete with inconsistencies that are directly opposed to many of the main provisions of the order. As much of the testimony of the proponent witnesses irrefutably established, the adoption of the committee agreement is unnecessary for the accomplishment of the purposes of Order R-111-P. Indeed, the provisions of the order and the committee agreement are so at odds that both would be rendered meaningless and would be incapable of being administered.

On an item by item basis, Texaco offers the following criticisms of the November 23, 1987 committee agreement:

## INTRODUCTION

The "Intention" of the agreement contravenes The New Mexico Oil and Gas Act as its general effect is to accord primacy to potash reserves in LMR areas at the expense of oil and gas reserves. To the contrary, the Oil and Gas Act directs the Commission and Division to prohibit <u>any</u> practices which reduce or tend to reduce the total quantity of oil or gas ultimately recovered from any bool while at the same time quarding against operations which "unduly" reduce the total quantity of

- 3 -

recoverable potash. (See, 70-2-3[A] and [F], N.M.S.A. [1978].) Nowhere in the Oil and Gas Act is there any authority which allows the development of potash reserves to the exclusion of hydrocarbon reserves. The perpetual prohibition against drilling in the LMR area would do just that. We would also make the following points:

- Creation of LMR's removes more lands from drilling than presently available.
- Creation of "drilling areas" outside of LMR's but within potash area is an illusory consideration: <u>fewer</u> lands will actually be available for permitting for drilling.
- We believe potash mining areas within the LMR are adequately protected by the procedures under R-111-A.
- The potash industry gains no additional safety factor under the letter agreement: drilling distance from mining activities is irrelevant in terms of subsidence and lost potash reserves. Notably, when a potash area is primary-mined, no subsidence occurs. Primary mining also allows the recovery of approximately 75% of the potash resource. Therefore, the loss of potash resources is minimal as compared to the <u>total</u> loss of oil and gas reserves under an absolute drilling ban in the LMR areas.

## I. THE POTASH AREA

- This section conforms R-111-A area to PLM definition of "Potash Area". This section is appropriate.

- 4 -

## II. DESIGNATION OF MINE RESERVES

A. The LMR designation process is confidential. What would in effect be the condemnation of oil and gas property interests should be subject to adversarial scrutiny (not necessarily <u>public</u> disclosure) by anyone with an affected property interest. Otherwise, the unilateral designation of LMR areas would likely be <u>arbitrary</u> and unsupported by <u>substantial</u> evidence, both of which are unlawful.

Data on which LMR areas would be based is often unreliable: We would note that in OCC Case 9143, a potash operator, in attempting to define its mineable reserves failed to honor a critical core-log which significantly altered the boundary of the barren area. Anyone with an affected property interest must have the opportunity to participate in the creation of an LMR area if they are created at all.

All oil and gas property interest owners are not similarly situated. Their interests are diverse. They cannot be treated as a <u>class</u>. Otherwise, due process and equal protection problems arise.

In designating LMP's, there is no requirement that a potash lessee actually own the potash reserves or have a right to mine the reserves subject to the LMR area. This is a highly objectionable provision.

Finally, neither the Oil Conservation Division nor the State Land Commissioner can lawfully delegate their respective authority to a process whereby LMR areas are determined solely by the potash operators and the PLM. By so doing, those public officers would cede their statutory responsibilities to ensure

- 5 -

that hydrocarbon reserves are not wasted and that state trust lands are administered for the optimal benefit of the state's beneficiary institutions. Thus, the very essence of the LMR designation process is unlawful as these public officers are concerned.

## III. DRILLING IN THE POTASH AREA

B. As explained above, neither the OCC, State Land Office or PLM can delegate their authority for approving APD's to a process that contravenes the Oil and Gas Act, the Arizona-New Mexico Enabling Act or the Interior Secretarial Order for drilling in potash areas. (See, Section 70-2-3 N.M.S.A. [1978], Enabling Act \$10, Interior Secretarial Order of October 28, 1986.)

## 1. Buffer Zone

The creation of the buffer zone is dependent upon the process for establishing LNR areas and thus has the same problems.

Also, in view of the geologic characteristics of the potash area and presently available and practicable technology, problems with respect to subsidence, gas migration, mine safety and undue waste of potash are avoidable. Therefore, the offset distances are unnecessary and do not achieve the purported goals of the agreement.

## 6. Abandoned Mine Workings

The abandonment and sealing plan is unnecessary. An oil and gas operator <u>cannot</u> accept responsibility for sealing a mine. As well, it is just as inappropriate to make drilling operations near abandoned mines subject to the unilateral veto of a potash lessee.

- 6 -

The safety certification accomplishes no purpose and is only provocative.

D. We disagree that the need for drilling islands is eliminated. This agreement cannot lawfully abolish drilling areas created by an Interior Secretarial Order.

IV. LOCATION OF WELLS AND NOTICE TO POTASH LESSEES

A. Requirement for unitization is vague, impracticable, accomplishes no apparent purpose and is likely impermissible under State Land Office and BLM Oil and Gas Regulations.

C. This subsection (as does Section IX C of the agreement) attempts to transfer liability by the agreement and is impermissible at law. Moreover, the language purports to make the owner of a lease interest liabile along with those "persons and/or entities involed in the development" whether the leaseholder is actually involved in drilling operations or not.

## SUMMARY

While the order proposed by the Oil Conservation Division is a commendable step in the right direction, it should not be adopted with any reference to the November 23, 1987 Agreement. The agreement while well-intentioned, is legally deficient and is irreconcilable with proposed Order R-111-P.

Because of that importance of this matter, we believe that further deliberations among the Division, the oil industry and potash industry are in order before a final amendment to Order R-111-A is proposed.
Respectfully submitted:

CAMPBELL & BLACK

Mr. Vic Lyon State of New Mexico Oil Conservation Division P. O. Box 2088 State Land Office Building Santa Fe, New Mexico 87504

Dear Vic:

Enclosed is some suggested language for your consideration and use in connection with the Potash-Oil Study Committee Agreement case. Feel free to use it as you wish. I did this just to give you my thoughts and ideas so it is not a statement from the Potash Industry. In fact, no one from the Industry has seen or approved it. I hope it will be helpful to you.

Best wishes.

Sincerely,

KEMP, SMATH / DUNCAN & HAMMOND By: C. High, Jr. es

## THE STATE OF NEW MEXICO ENERGY, MINERALS AND NATURAL RESOURCES DEPARTMENT OIL CONSERVATION COMMISSION

IN THE MATTER OF THE HEARING ) CALLED BY THE OIL CONSERVATION ) COMMISSION OF NEW MEXICO FOR ) THE PURPOSE OF CONSIDERING; ) AGREEMENT REACHED BY THE ) POTASH-OIL AND GAS STUDY ) COMMITTEE ON NOVEMBER 23, 1987 ) TO REVISE, AMEND AND RECODIFY ) ORDER R-111, AS AMENDED )

### ORDER OF THE COMMISSION

This cause came on for hearing at 9:00 a.m. on February 18, 1987, in Santa Fe, New Mexico, before the Oil Conservation Commission of New Mexico, hereinafter referred to as the "Commission".

NOW, on this \_\_\_\_\_ day of March, 1987, the commission, a quorum being present, having considered the <u>Statement of</u> <u>Agreement Between the Potash Industry and Oil and Gas Industry</u> <u>on Concurrent Operations in the Potash Area in Eddy and Lea</u> <u>Counties, New Mexico</u>, a copy of which is attached hereto as <u>Exhibit A</u>, as well as the testimony presented and exhibits received at the hearing and being fully advised in the premises,

FINDS THAT;

1. Public notice has been given as required by law and the Commission has jurisdiction of this cause and the subject matter thereof.

2. (Recite the history of meetings between the two Industries and the opportunities for everyone to participate as explained by Vic Lyon at the hearing and other factual findings).

3. The Agreement under consideration represents the efforts of numerous representatives from each Industry over many months and is intended to resolve many of the disputes that have arisen as a result of concurrent oil and gas drilling activities in the vicinity of underground potash mining.

4. The Industry representatives involved in the discussions leading up to the Agreement are knowledgeable of the safety issues involved when methane gas enters an underground mining operation. They are also knowledgeable of the technology and methods available to each to deal with these hazards while allowing maximum concurrent development of potash, oil and gas.

5. The concurrent development of natural resources, particularly when there is a safety risk involved, requires that there be limits on each Industry.

6. The protection of the citizens of the State of New Mexico, whether performing work in an underground potash mine or on an oil or gas rig, is paramount to the uncontrolled development of natural resources.

7. The agreement of Industry representatives on how our State's natural resources can be concurrently developed in a safe and orderly manner provides strong and useful guidance to the Commission.

- 2 -

8. The Agreement reached by the two Industries reflects compromises on issues known to be critical to each in the express hope of reducing the time spent by the State in resolving these issues while our natural resources go undeveloped.

9. The protection of correlative rights, the promotion of conservation, and the prevention of waste require that certain areas of potash deposits, called "life-of-mine reserves", be protected from oil and gas drilling activities and that other areas specified in the Agreement be made available for oil and gas activities.

10. The technological and other developments that have occurred since the adoption of Order R-111 require that it be revised to reflect modern day standards and concerns.

11. The terms set forth in the Agreement, except as modified below, will permit the development of oil and gas and thus prevent waste of hydrocarbon resources without undue waste of potash as directed by the Oil and Gas Act, 70-2-12(17) NMSA. The adoption of these terms, as modified, will therefore prevent the waste of either potash or oil and gas.

IT IS THEREFORE ORDERED THAT:

This Order shall be known as The Rules and Regulations Governing the Exploration and Development of Oil and Gas in the Potash Area in Eddy and Lea Counties, New Mexico.

- 3 -

#### OBJECTIVE

I.

The objectives of these Rules and Regulations are to prevent waste, protect correlative rights, assure maximum conservation of the oil, gas and potash resources of New Mexico, and permit the economic recovery of oil, gas and potash minerals in the area hereinafter defined while protecting the citizens of the State of New Mexico from unreasonable and unnecessary safety hazards.

## II.

## POTASH AREA

A. The area covered by these Rules and Regulations shall be known as the "Potash Area".

B. The "Potash Area" includes those tracts of land in Eddy and Lea Counties, New Mexico, from the surface downward, which are designated as a "potash area" by the Secretary of the Interior in Section V of the Order dated October 28, 1986 [51 Fed.Reg. 39426].

C. The "potash area" covered by these Rules and Regulations may be revised from time to time by the Commission after due notice and hearing at the regular pool nomenclature hearings to reflect any subsequent changes by the Secretary of the Interior.

## III.

## DESIGNATION OF MINE RESERVES

A. Within ninety (90) days of the effective date of this Order and annually thereafter by January 31 if revised, each

- 4 -

potash lessee in the Potash Area, without regard to whether the lease covers State or Federal land, shall file with the District Manager, Bureau of Land Management ("BLM") and the Director, New Mexico Oil Conservation Division ("OCD") a designation of the potash deposits considered by the potash lessee to be its life-of-mine reserves ("LMR"). For purposes this Order, "life-of-mine reserves" means those potash of deposits within the Potash Area reasonably believed by the potash lessee to contain potash ore in sufficient thickness and grade to be minable using current day mining methods, equipment, and technology. Information used by the potash lessee in identifying its LMR shall be filed with the BLM and OCD but will be considered privileged and confidential "trade secrets commercial...information" and and not subject to public disclosure.

eer ad led

B. An authorized officer of the BLM, in cooperation with the OCD, or an official of the OCD in the absence of a worksharing agreement with the BLM, shall review the information submitted by each potash lessee in support of its LMR designation and verify, upon request, that the data used by the potash lessee in establishing the boundaries of its LMR  $\frac{15}{4\pi}$  consistent with data available to the BLM and/or OCD. Any disputes concerning the boundary of a designated LMR shall be first heard and resolved in accordance with the Department of Interior's Hearings and Appeals Procedure, 43 C.R.F. Part 4

- 5 -

(1986). The Commission shall review any decision concerning State land for consistency with this Order and may adopt or amend any such decision as necessary to carry out the intent of this Order.

C. A potash lessee may amend its designated LMR by filing a revised designation with the BLM and OCD accompanied by the information referred to in Section A above. Such amendments must be filed by January 31 next following the date the additional data becomes available.

D. An authorized officer of the BLM and/or OCD shall commit the designated LMR of each potash lessee to a map(s) of suitable scale and thereafter revise the map(s) as necessary to reflect the latest amendments to any designated LMR's. These map(s) shall be considered privileged and confidential and exempt from disclosure and will be used only for the purposes of this Order.

# IV.

# DRILLING IN THE POTASH AREA

A. All drilling of oil and gas wells in the Potash Area shall be subject to these Rules and Regulations.

B. No wells will be drilled for oil or gas at a location which, in the opinion of the Commission, or its duly authorized representative, would result in undue waste of potash deposits or constitute a hazard to or interfere unduly with potash deposits.

- 6 -

C. No mining operations will be conducted in the Potash Area that would, in the opinion of the Commission or its duly authorized representative, constitute a hazard to oil or gas production, or that would unreasonably interfere with the development and production from any oil or gas pool

D. Applications for permits to drill on federal lands will be processed for approval by the BLM. APD's on State or patented lands will be processed by the OCD and in the case of State lands, in collaboration with the Commissioner of Public Lands. The Division will first ascertain from the BLM whether the proposed drilling location is within or outside of any designated LMR. Approval or denial of APD's will be determined in accordance with the following policies:

- 1. <u>LMR and Buffer Zone</u>. No oil or gas well shall be allowed from a surface location: (a) within the LMR of any potash lessee; (b) within one-fourth (1/4) mile, or a distance equal to the depth of the ore plus ten percent (10%), whichever is greater, of the LMR of any potash lessee; or (c) where the well casing will pass within one-fourth (1/4) mile, or a distance equal to the depth of the ore plus ten percent (10%), whichever is greater, of the LMR of any potash lessee.
- 2. Outside Buffer Zone But Within One-Half (1/2) mile of LMR. An APD for an oil or gas well at a location more than one-fourth (1/4) mile, or a distance equal to the depth of the ore plus ten percent (10%), whichever is greater, but less than one-half (1/2) mile from the LMR of any potash lessee may be approved only if: (a) the bottom hole location does not extend below the base of the Delaware Mountain Group, and (b) the well is drilled in accordance with the cementing and casing requirements of this Order.
- 3. <u>More Than One-Half Mile But Less Than One Mile From</u> <u>LMR</u>. An APD for an oil or gas well at a location more than one-half (1/2) mile but less than one mile from

- 7 -

7

the LMR of any potash lessee may be approved regardless of the depth of the bottom hole location provided: (a) wells with bottom hole locations below the base of the Delaware Mountain Group are drilled in accordance with the cementing and casing requirements of this Order, and (b) wells to bottom hole locations above the base of the Delaware Mountain Group may be drilled without regard to the cementing and casing requirements of this Order but must be drilled in accordance with then current Industry safety standards.

- 4. <u>More Than One Mile From LMR</u>. An APD for an oil or gas well at a location more than one mile from the LMR of any potash lessee may be approved regardless of the depth of the bottom hole location and without regard to the cementing and casing requirements of this Order.
- 5. <u>Open Mine Workings</u>. No oil or gas well shall be allowed from any location where the well casing will pass within one-fourth (1/4) mile or a distance equal to the depth of the ore plus ten percent (10%), whichever is greater, of any open mine workings.
- 6. <u>Abandoned Mine Workings</u>. No oil or gas well shall be allowed from any location where the well casing will pass through or within one-fourth (1/4) of a mile or a distance equal to the depth of the ore plus ten percent (10%), whichever is greater, of any abandoned mine workings that are connected to an existing mine by an opening or barrier of one-hundred (100) feet or less unless the APD is accompanied by the sealing and safety plan and certification described in Paragraph E below.
- 7. An APD for a directionally drilled oil or gas well to a bottom hole location underlying the LMR of any potash lessee may be approved subject to the limitations and requirements set forth in Paragraphs 1 - 6 above. Directionally drilled holes shall be drilled vertically until they have completely penetrated Marker Bed No. 126 (U.S.G.S.) of the Salado Formation at which time they may be deviated.

E. An oil and gas operator desiring to drill a well to a bottom hole location that does not extend below the base of the Delaware Mountain Group from a surface location where the well casing will pass through or within one-fourth (1/4) of a mile or a distance equal to the depth of the ore plus ten percent (10%), whichever is greater, of abandoned mine workings that are connected to an existing mine by any opening or a barrier of one-hundred (100) feet or less shall prepare and submit to all affected potash lessees a plan and program for sealing off the area to be penetrated from other mine workings. Approval of any such plan shall be in the sole discretion of the affected potash lessees. Any approved plan shall be attached by the oil and gas operator to the APD for filing with the OCC, and/or BLM. The oil and gas operator shall also complete a certification in the form prescribed by the OCC and/or BLM that the drilling of such well will not create a safety hazard to affected potash lessees.

#### V.

## LOCATION OF WELLS AND NOTICE TO POTASH LESSEE

A. The BLM, upon request, will advise oil and gas lessees of the surface locations where wells will be allowed to develop the leases. Oil or gas leases covering areas designated a LMR by a potash lessee will be unitized to the extent possible with other areas where drilling is allowed.

B. An oil or gas operator desiring to drill an oil or gas well in the Potash Area or within one (1) mile of a potash lease shall prepare and file an APD with the OCC and/or BLM along with a map or plat showing the location of the proposed well. One copy of the APD and map or plat shall be served by

- 9 -

registered mail, return receipt requested, on all potash leaseholders within one (1) mile of the proposed well location. However, if the APD is for an oil or gas well that will penetrate abandoned mine workings, all potash leaseholders in the Potash Area shall be notified. Proof of such service shall be attached to the APD and filed with the OCC and/or Within twenty (20) days of service of an APD and required BLM. documents, any potash leaseholder within one (1) mile of the proposed well location (or any affected potash lessee if the proposed well will penetrate abandoned mine workings) may file an objection with the OCC to the proposed well. If the objections cannot be resolved by agreement of the parties, the matter shall be referred for hearing before the OCC.

C. The failure of a potash leaseholder to object to a well location or its agreement to the drilling locations referred to in this Agreement shall not constitute a release of liability. Oil and gas leaseholders and those persons and/or entities involved in the development of the lease shall be responsible as provided by law for any damages caused by them to any person by the release of gases or liquids into the strata or atmosphere as a result of drilling activities.

### FILING OF WELL SURVEYS

The OCC may require an oil and gas operator to file a certified directional survey from the surface to a point below the lowest known potash bearing horizon on all wells drilled in the Potash Area. All encounters with flammable gases, including  $H_2S$ , shall be reported by the operator to the OCC.

x.

### ADDITIONAL SAFETY REQUIREMENTS AND EMERGENCY ACTION

A. All oil and gas drilling activities within the Potash Area shall be performed using appropriate technology, equipment, and procedures to reduce the hazards of such activities to underground mines and miners and be conducted in accordance with the prudent operator standard.

B. Only the minimum number of wells necessary to develop an oil or gas lease will be allowed within the Potash Area.

C. In the event the increased oil and gas drilling activities allowed by this Order result in a safety hazard or if data developed in the course of such increased activities

- 11 -

make it reasonably appear that such activities are or will become a hazard to underground miners or mining activities, the BLM and/or OCC may, upon request, initiate proceedings in accordance with NMSA 70-2-23 and/or other applicable laws and regulations to review such data and take whatever emergency steps are found necessary to eliminate such hazard. Potash lessees may, in addition, initiate actions for injunctive relief under NMSA 70-2-29. The taking or failure to take such action by the OCC or any potash lessee shall not relieve the oil and gas lessee from liability for any damages caused by its oil and gas activities.

### XI.

## APPLICABILITY OF STATEWIDE RULES AND REGULATIONS

All general statewide rules and regulations of the Oil Conservation Commission governing the development, operation, and production of oil and gas in the State of New Mexico not inconsistent or in conflict herewith are hereby adopted and made applicable to the areas described herein.

DONE AT SANTA FE, NEW MEXICO on the day and year hereinabove designated.

## STATE OF NEW MEXICO

2199L-2

# COMMENTS OF THE CARLSBAD POTASH INDUSTRY TO THE NEW MEXICO OIL CONSERVATION DIVISION POTASH-OIL STUDY COMMITTEE ON THE NEED FOR REVISIONS IN THE RULES AND REGULATIONS FOR DRILLING OIL AND GAS WELLS IN THE POTASH BASIN

## I. Introduction

The Carlsbad Potash Industry ("Industry") welcomes this opportunity to present its comments and recommendations to the New Mexico Oil Conservation Division Potash-Oil Study Committee ("Study Committee") on the need for revisions in the current rules and regulations governing the drilling of oil and gas wells in the Potash Basin.

The mine operators concurring in these Industry comments and recommendations are AMAX Chemical Corporation, International Minerals and Chemical Corporation, Lundberg Industries, Ltd., Mississippi Chemical Corporation, New Mexico Potash Corporation, Noranda Minerals, Inc., and Western Ag-Minerals Company, all of which have underground potash mining operations or potash properties in the Potash Basin near Carlsbad, New Mexico. Collectively, these companies produce 100% of all potash mined in New Mexico and hold 100% of the potassium leases granted by the State of New Mexico. They also hold 98.9% of all potassium leases in the Potash Basin, including both Federal and State. Accordingly, the views expressed in these comments clearly reflect the unanimous position of the entire Potash Industry.

Our concern with the existing rules and regulations, simply stated, is that they have become obsolete and no longer adequately protect our mines and miners from the hazards associated with the increased oil and gas drilling activities that has occurred over the years. We have expressed this concern on numerous occasions to the New Mexico Oil Conservation Division ("OCD") and the Bureau of Land Management, U.S. Department of Interior ("BLM") the and appreciate the initiative of the OCD, and in particular its director, Mr. R. L. Stamets, for establishing this Committee to study the many issues involved and redetermine, under today's standards, where, when and how both oil and gas and potash development in the Basin can proceed in a safe and efficient manner. We are confident that once everyone fully understands the nature of our operations and the basis for our concern over the existing rules and regulations, the need for revisions will become clear. We are also hopeful that through this process, we will be able to achieve a mutual understanding of the many issues involved and reach an agreement on revisions that will be acceptable to everyone involved.

## II. Special Characteristics of the Mining Industry

In evaluating the many issues involved, as well as our concerns, it is important that everyone understand the nature of underground mining in general and potash mining in particular. We are unique in a number of ways.

- 2 -

## A. Limited Ore Reserves

First of all, we are a geographically limited industry. area of potash deposits in Southeastern New Mexico, The commonly called the Potash Basin, is the only known deposit of potash in the United States that can be mined through conventional mining methods. These deposits were discovered in 1925 after several years of exploration by the U.S. Geological Survey and private industry to find a replacement source for potash when German imports ceased with the outbreak of World War I. Smaller deposits have been found in Utah and California but, for a number of reasons, these cannot be mined using conventional methods. As a result, mines in the Potash Basin account for 87% of all potash mined in the United States [Mineral Industry Surveys, U.S. Department of the Interior, Bureau of Mines (1984), attached as Exhibit 1].

### B. Types and Characteristics of Potash Ore

There are two types of potash ore found in the Potash Basin. The first and primary ore is sylvite, which is or has been mined by all of the producers in the Basin. The second type of ore is langbeinite, which is mined by only two operators. This is a rare ore, and the Potash Basin is the only known commercial reserve of this commodity in the Western Hemisphere. Both of these ores are non-toxic, non-explosive, non-flammable, water soluble, and are used in the production of fertilizer. There is no known substitute for potash as an essential plant nutrient.

- 3 -

# C. Underground Mine Development and Operations

Our method of operation also makes us unique. The potash deposits in the Basin are found in the McNutt Member of the Salado Formation, so we work underground at depths ranging from about 800 to more than 2000 feet. Twelve (12) bedded ore deposit horizons have been identified in the McNutt Member and are numbered sequentially upward, with the twelfth ore zone being the one closest to the surface and the first ore zone being the deepest underground [see Figure 5, page 12, George B. Griswold, Geology of the Carlsbad Mining District (1982),attached as Exhibit 2]. These ore horizons comprise only about 3% to 5% of the McNutt Member [see Chaturvedi, Lokesh, Occurrence of Gases in the Salado Formation (1984), page 4. attached as Exhibit 3], and range in thickness from one (1) foot to ten (10) feet [Exhibit 2, page 11, Table 1, Salado].

## 1. Access Through Vertical Shafts

To reach these deposits, each of the potash mines has sunk from two to five shafts vertically into the ground down to whatever depth was required to reach the deposits at their mine site. These shafts are divided into vertical compartments with one or two compartments generally used as part of the mine ventilation system and the other compartments used for elevator-type devices that hoist miners, supplies, and ore in and out of the mine.

- 4 -

## 2. Development of Underground Working Areas

Horizontally off of these shafts are the working areas of the mine. The sinking of a shaft is extremely expensive, so they are strategically located so that mine development can proceed in all directions from the shaft. These working areas began as tunnels leading away from the shaft into whatever area of deposits the mine operator determined to mine. Other tunnels are then mined off of existing tunnels in all directions so that, after first mining, the only things left are pillars of predetermined size at specified distances to support the ceiling or overburden, as it is called. Because of the length of time mining has been going on in the Basin, the area of underground workings in the mines is quite large and may cover many square miles. In fact, it is not unusual to go into a mine and then travel several miles from the bottom of the shaft to the area where ore is being removed from the ore body.

## 3. Final Mining and Ground Subsidence

The support pillars left by this first or developmental mining also contain large amounts of potash ore. Although the amounts vary depending upon a number of factors, most mines traditionally plan to recover from 50-70 percent of the ore during the first phase of mining. The remaining 30-50 percent of the ore is not, however, wasted. When first mining is completed in a particular deposit, the pillars are then mined so that this additional ore can be recovered. This removal of

- 5 -

support for the overburden then causes a slow subsidence that eventually fills the void created by the removal of the potash ore. This displacement extends all the way to the surface at an angle of about 45° from the mined out area. A study discussing the extent of ground movement caused by subsidence is attached as Exhibit 4.

# 4. Mining Equipment and Support Facilities

The actual mining of the ore is performed with either continuous mining machines or by conventional drilling and A continuous miner is а blasting techniques. specially designed vehicle with drum-like devices on the front that rotate and cut the ore with teeth-like bits. A photograph of one type of continuous miner is included as Exhibit 5. As the ore is removed from the ore body by the continuous miner, it falls onto a conveyor system and is moved to the rear of the continuous miner, where it is dropped into a "shuttle" or "ram" car for transport to a conveyor belt system that takes the ore to the bottom of the hoist. A photograph of one type of these vehicles is also included as Exhibit 5. From the bottom of the shaft, the ore is loaded onto a hoist and hoisted to the surface for refining.

The equipment used in underground mining, as shown by Exhibit 5, is heavy equipment. Other types of vehicles are also used to transport people and equipment. These pieces of equipment are either electrically powered or diesel powered.

- 6 -

One mine has an electrically powered trolley system with a track system throughout the mine. In most instances, equipment to be used underground must be disassembled so that it will fit into the shaft for lowering underground and then reassembled for use once it is underground. All of the mines also maintain support facilities underground. There are generally one or more maintenance shops located underground with the same type equipment you would find in any typical maintenance shop. These maintenance shops perform the full range of maintenance activities, including complete engine and equipment overhauls.

## 5. Ventilation of Underground Working Areas

Ventilation to the underground working areas is provided by main fans which either push or pull surface ambient air into the mine, where it is then disbursed through active mine workings with booster fans. Directional control of the air, as well as the volume, is carefully controlled so that fresh air from the surface is routed to places where work is being performed and then routed out of the mines back to a shaft where it exits to the surface. Because of the obvious importance of oxygen to human life, this aspect of underground mining, as well as many others which we will talk about later, are heavily regulated by both the federal and state governments.

# III. Safety of Miners from An Industry Perspective

These unique features of our Industry and the increased hazards inherent in underground work require, and we believe

- 7 -

rightfully so, that the safety of our employees take precedence over production and development considerations. This is a clearly stated Federal policy and is perhaps best illustrated by the following statements of Senators Harrison Williams and Jacob Javits when the current Federal Mine Safety and Health Act was under consideration in 1977:

"Our country is now turning to address our natural energy shortage. The President has already sent to us a comprehensive plan to increase the development and exploitation of our energy and mineral reserves. I believe that an effective mine safety and health program must be put in place first - and must be the firm foundation upon which we will build our national energy program. Otherwise, we will continue to pay for our energy and minerals with the dreadful currency of human lives and limbs.

"Our national energy needs should not be met at the expense of our Nation's miners and their families. With the possibility of greatly increased mineral extraction on the near horizon, the time has come for reform of our inadequate mine safety and health program. Our miners should have to wait no longer. Our Nation should want to wait no longer."

\* \* \*

"This bill is intended to strike a new balance in the longstanding antagonistic goals of maximizing production of energy and mineral resources on the one hand, and, on the other hand, affording the maximum safety and health protection for the workers who extract those resources in what all recognize is inherently a highly hazardous occupation."

[Congressional Record - Senate, June 20, 1977, p. 10204, attached as Exhibit 6].

While we like to think we have always struck this balance in favor of safety, we are nevertheless aware of and affected by the many disasters that have occurred in underground mines. The record of these is long and includes the loss of thousands of lives. Of particular concern to us, as it should be to the Study Committee, is the fact that the single most frequent cause of these disasters has been an unexpected encounter or accumulation of methane or some other flammable gas.

A. Characteristics of Methane and Hydrogen Sulfide Gases

Methane, as everyone on the Study Committee knows, is a colorless, odorless, tasteless and non-poisonous gas that is highly flammable and explosive in concentrations containing as little as 5% methane and 12.1% oxygen [See Coward, H.F. and Jones, G.W. Limits of Inflammability of Gases and Vapors, U.S. Bureau of Mines Bulletin No. 503 (1952), pp. 37-48, attached as Exhibit 7]. It is lighter than air and when present in an underground mine will generally accumulate near the roof or in high places. Once it becomes thoroughly mixed with mine air it will be found uniformly distributed across the moving air current and will not separate or stratify even if the air becomes still. [Forbes, J.J. and Grove, G.W., Mine Gases and Methods for Detecting Them, U.S. Bureau of Mines Miners' Circular 33 (1954), pp. 6-7, attached as Exhibit 8].

The characteristics of hydrogen sulfide are likewise well known. It is a colorless, toxic, flammable gas that has an odor of rotten eggs at low concentrations. Air that contains 4.3 to 45 percent hydrogen sulfide will ignite when subjected to ordinary flames and will explode. It is also very poisonous

- 9 -

and will cause eye and respiratory tract irritation after exposure of one hour to concentrations as low as .005 to .01 percent (50 to 100 ppm). Concentrations above .07 percent (700 ppm) will cause а loss of consciousness, paralyze the respiratory system and cause death. Although hydrogen sulfide has a distinctive odor, the sense of smell cannot be relied a means of detection because after one or upon as two inhalations, the olfactory nerves become paralyzed and the hydrogen sulfide odor can no longer be detected [Forbes, J.J. Grove, G.W., and Mine Gases and Methods for Detecting Them, Bureau of Mines Miners' Circular 33 (1954), pp. 11-13, U.S. attached as Exhibit 9].

# B. Hazards of Flammable Gas in an Underground Mine

It would be nice if we could say that the many mine disasters caused by these hazardous gases occurred in some deep, dark coal mine during an earlier, less sophisticated period of time where today's technology, knowledge and safety enforcement were not present. In fact, there is a tendency among people outside the mining industry to view these disasters in that perspective. However, that simply is not the case. A review of three selected examples of contemporary gas related mine disasters will illustrate this point. All three of the mines involved utilize state-of-the-art technology and engineering practices and were heavily regulated by federal and state mine safety agencies prior to the explosions.

- 10 -

The first occurred on August 27, 1963 at the Cane Creek potash mine in Grand County, Utah. A major inrush of flammable gas occurred from a single working face into a decline drift (tunnel) during routine mining operations. The gas was carried along the tunnel by the ventilation system, and about 20 minutes later reached the main shop area and ignited from one of three ignition sources. Twenty-five employees were working throughout the mine and 18 of them died from explosive forces, flames or asphyxiation. The methane entered the mine during blasting in the strata above the targeted potash deposits. The source of the methane was believed to be a clastic oil shale geological formation adjacent to the salt beds.

This incident illustrates the increased hazard of methane when encountered in an enclosed, underground environment. In addition to the fatalities and the injuries caused by the explosion, the containment of the explosion within the interior of the mine created such a force that it caused severe damage throughout the mine and up the shaft to the surface. One surface employee was injured when a wooden shed in the mine yard on the surface was destroyed by the blast pressure wave coming out of the shaft opening. The details of this explosion are set forth in an investigatory report by the U.S. Bureau of Mines, a portion of which is attached as Exhibit 10. А complete copy will be provided upon request.

- 11 -

The second example is more recent and occurred in domal salt deposits on June 8, 1979 at the Belle Isle Salt Mine of Cargill, Inc. near Franklin, Louisiana.

At the end of an evening shift, a gas outburst occurred following a regular production blast in the southeast part of the mine. Approximately ten minutes later, the methane gas had diluted to the explosive range and reached an electrical panel ignition source some distance away from the working face. The concussion from the resulting explosion caused four fatalities and one other employee died from concussion injuries and exposure to carbon monoxide. In addition, several of the 17 survivors suffered serious or permanently disabling injuries. Destruction of mine facilities and equipment was estimated to be in the millions of dollars.

This case, too, illustrates the tremendous amount of force generated by an explosion and the hazard it creates in an enclosed underground mine. The five victims of this explosion were located at distances of 2600 feet to 4600 feet away from the explosion area. One federal inspector calculated that the pressure wave velocities from the explosion exceeded 300 miles per hour through the underground workings and temperatures were more than 2000° Fahrenheit in the explosion fire-cloud. Selected portions of the final report of the U.S. Department of Labor, Mine Safety and Health Administration, on this

- 12 -

disaster is attached as Exhibit 11. Copies of photographs attached to the Report illustrate the force of the explosion.

The third and final example is still more recent and occurred on April 15, 1981 at the Dutch Creek No. 1 coal mine in Pitkin County, Colorado. Late in the afternoon, a sudden rush of methane occurred during regular mining operations in a Similar occurrences had been working face. encountered previously and procedures had been adopted and put in place to dilute and remove the gas concentrations. The work crew in the immediate area was believed to have been implementing these procedures when a defective explosion proof switch arced as equipment lights were turned off. The resulting explosion killed the six members of the crew and nine additional employees at remote locations throughout the mine. This mine, like all coal mines, was being operated under Federal gassy mine regulations requiring approved, electrically-permissible equipment and special ventilation systems. Despite this, a minor error in the assembly of a light switch enclosure, combined with the methane encounter, caused the disaster. It: should also be noted that the methane involved in this explosion was not the slow emanation of methane commonly associated with gassy coal mines. Instead, the methane entered the mine in a sudden outburst caused by relief of stresses in the strata surrounding the ore body. The investigatory report of this incident is too voluminous to attach as an exhibit but we will be glad to provide a copy to anyone who wants to see it.

- 13 -

These examples vividly demonstrate the potential dangers present whenever flammable qas is introduced into an underground mine environment. In all three of these examples, no one believed such an event could occur. Local knowledge of mine conditions, the contemporary technology being used, and the extensive regulation by both federal and state safety agencies may have reduced the odds but were not enough to prevent the unexpected events that occurred. In two of these examples, the flammable gas was not contained in the material being mined and was never supposed to be encountered during mining operations. However, in the Cane Creek example, the methane migrated through salt structures from adjacent formations and at the Belle Isle mine the gas was encountered in geological discontinuity intersected by а advancing underground workings. In the third example at the Dutch Creek mine, the mine was accustomed to controlling the traditional continuous emanation of methane from the ore body but was unable to safely control methane encountered from another, unexpected source.

# C. Lack of Naturally Occurring Flammable Gas Hazard in the Potash Basin

In the Potash Basin we are fortunate that we have never had an accident involving methane, hydrogen sulfide, or any other flammable gas and because of the geology of the Basin, we have no expectation that such an event will ever occur. The natural occurrence of flammable gases in the Salado Formation where we

- 14 -

mine has been carefully and extensively studied and in each case the conclusion was reached that these gases do not constitute a hazard to our miners or our underground mining operations.

The first of these studies, Investigation Into the Occurrence of Gas Pressure Above the First and Tenth Ore Zones in the Potash District, Carlsbad, New Mexico, was conducted by the U.S. Bureau of Mines in 1963 and is included as an exhibit to Exhibit 2. The second, entitled Geology of the Carlsbad Potash Mining District (with Emphasis on Brine and Inert Gases Adjacent to or Within the Ore Beds), was performed for the Industry in 1982 by Dr. George B. Griswold, a well known geologist familiar with the Potash Basin, and is attached as Exhibit 2. A third study, Occurrence of Gases in the Salado Formation, was conducted by Dr. Lokesh Chaturvedi of the New Mexico Health and Environment Department for the Waste Isolation Pilot Plant ("WIPP") in 1984 and is attached as Exhibit 3.

These studies identified several reasons why the naturally occurring gases in the Salado are not a hazard. First, the gases encountered are primarily nitrogen with only minor amounts of methane and generally less than two percent oxygen. Even though the small amounts of methane are well below the hazardous level, the high nitrogen, low oxygen concentrations

- 15 -

in which they occur are not capable of forming flammable mixtures with air as shown in Figure 22, Exhibit 7, p. 47.

Second, the minor amounts of gases encountered are intentionally released into the mine atmosphere through pressure relief holes where they are rapidly diluted by the mine ventilation system. Pressure relief holes are holes approximately 1 5/8" in diameter that are drilled into the back (ceiling) of a mine from 10 to 30 feet deep. These holes are drilled by all of the operators and are designed to relieve pressures caused by stress changes associated with mine development and thereby reduce the risk of a roof fall.

Third, and perhaps most importantly, there is no geological source for large concentrations of methane in the Salado. As explained by Dr. Griswold in his study of the Basin [Exhibit 2], and as many of you know, the Salado was formed through a cyclical nature of deposition starting with a thin layer of clay covered by a thicker but still thin sheath of anhydrite followed by a much thicker bed of halite. The first phase of the cycle, the clay seam, represents an original drying and erosional surface at the top of the underlying halite due to the fact that clay minerals tend to concentrate at the surface. Sea water then re-entered the area, causing additional solution of the underlying halite. Clay buildup continued with the settling of fine particles carried in with

- 16 -

the sea water. Third, the evaporation process recommenced, resulting in the formation and deposition of aragonite and then gypsum, which were later converted to dolomite and anhydrite by diagenetic processes. The next phase saw the halite start to crystallize and the sea water became highly concentrated by evaporation. In the final phase, drying continued and additional halite was formed. The surface was dry at this point and blowing winds and occasional rainfalls deposited more detrital material to the evaporation pan. Clay also began to be deposited with the halite. The cycle was then complete, setting the stage for the next cycle.

The only period during these formation cycles when marine organic life could have existed was during the second phase when sea water re-entered the area. These marine waters were more saline than the open sea and, according to Dr. Griswold, were too hostile for any form of marine life other than algae and microscopic organisms. Higher order organisms could not have existed and no fossil remains have been identified in the Salado. This algae was identified by Dr. Griswold as being the probable source of the minor amounts of methane we encounter in the Basin.

This geological development not only rules out the presence of large concentrations of methane in the Salado, but protects us from any gases that may be present in the Guadalupian strata below. As noted by Dr. Griswold, the McNutt member of the

- 17 -

Salado, where our deposits are located, is underlaid with an impermeable barrier of halite ranging from 400 to 1500 feet thick and overlaid with a similar layer of halite ranging from 100 to 500 feet thick [Exhibit 2, p. 19].

IV. Hazards Created by Oil and Gas Activity

## A. Possible Release of Flammable Gases

The concern we have about oil and gas drilling activities in the Basin, of course, is that methane, hydrogen sulfide, or some other hazardous gas will be released into the Salado Formation and either migrate into our underground workings or be encountered at some future time and cause an explosion. We know that such releases have already occurred in the Hobbs area. As a result, the Salado in that area is charged with methane and has been since the 1950s. This came out in testimony before the Oil Conservation Commission in 1955 in Case No. 862 when Mr. S.J. Stanley, an engineer for the OCC, admitted that:

"It has been definitely proven in the oil business that the salt section is charged in the Monument and Hobbs Pool and charged with gas. The charging of oil and gas in these pools was probably man-made by casing leaks." [Transcript of Hearing, p. 6]

A copy of the transcript of this hearing, which includes Mr. Stanley's testimony, is attached as Exhibit 12.

## B. Likelihood of Releases Occurring

We recognize that many, if not all, of the gas releases in the Hobbs area occurred prior to the adoption of R-111-A. We do not, however, believe that the current provisions of R-111-A

- 18 -

are adequate to protect our mines and miners from similar occurrences in the future. There are several reasons why we believe this.

# 1. Wells in Close Proximity to Mining

First, R-111-A, a copy of which is attached as Exhibit 13, was issued in 1955 without the benefit of current knowledge on the hazards involved when methane or hydrogen sulfide gases are introduced into an underground mining environment. Since that time, a considerable amount of information and knowledge has been gained about the effects and risks of these and other flammable gases on underground miners. We now know they are extremely hazardous in all mines, not just coal mines, and can cause an explosion and death even when stringent safety practices are in place. R-111-A seems to recognize this potential because it prohibits any activity by either industry that "would . . . constitute a hazard" to the other [Exhibit 13, p. 2, Art. III]. However, in the 31 years since it was adopted, no standards have developed for use been in determining if or when a proposed oil or gas well will constitute a hazard to potash mining. We do not even know how far an oil or gas well must be from a potash mine to avoid the release and migration of hazardous gases into mine workings or ore deposits. In fact, under R-111-A, as it currently exists, a proposed oil or gas well will generally be approved without investigation or inquiry by the OCD or oil or gas operator as

- 19 -

to its impact on the safety of miners unless a timely protest is filed by a mine operator.

Any procedure, such as this, which would allow an oil or gas well to be drilled in close proximity to an underground mine where people are working or through ore deposits where they may be working in the future without an independent and automatic inquiry into its effect on safety is, in our opinion, dangerous and out of step with modern day standards for human safety. We also believe it is in conflict with the intent and purpose of State mine safety and health laws that the Energy and Minerals Department is also charged with enforcing [See, e.g., NMSA §§69-27-1 and 69-27-6, attached as Exhibit 14].

# 2. Oil and Gas Accidents and Blowouts

Secondly, the well casing program required by R-111-A, while providing some protection, is inadequate without more to protect us against the hazards involved. In the absence of additional safeguards, such as a spacing requirement between oil or gas wells and ore deposits, we must assume that the casing and cementing program will always be 100% effective in preventing the release of hazardous gases into the Salado. We do not believe that is true and do not believe the OCD or any responsible oil or gas operator will ever represent to us that it is true. Accidents happen and when they do gases may be released into the surrounding strata, perhaps unknowingly, and either migrate into mine workings or be encountered during mining at some future date. No other conclusion is possible,

- 20 -

we submit, when you review the number and magnitude of the accidents that have already occurred in and around the Potash Basin.

Although information on oil or gas mishaps is difficult to obtain, we are aware of at least 16 instances where there has been a blowout and/or fire during drilling operations. A list of these and a map showing their location in relation to the Potash Basin is attached as Exhibit 15. More detailed information on two of these mishaps, which were within the Known Potash Area, is attached as Exhibit 16. Information on another blowout which occurred at only 3,047 feet is attached as Exhibit 17. Information on two deep wells where blowouts occurred is included as Exhibit 18. Miscellaneous additional information on these and several other accidents on which we could find no records is attached as Exhibit 19.

3. Known Instances of Oil Seepage and Migration

Third, we are concerned that even in the absence of an accident, hazardous gases may migrate upward along the outside of the casing and become a hazard to us when encountered. R-111-A offers us no protection against such a possibility or, for that matter, protection against the migration of gases accidentally released. This is particularly troubling because the available evidence clearly shows the potential for at least some migration in the Basin.

The clearest evidence of this possibility, of course, is the oil seepage that occurred at the Mississippi Chemical and

- 21 -

Lundberg Industry mines. The oil seepage at the MCC mine was discovered near what is known as a "breccia pipe". This is a vertical pipe or chimney-type displacement of the geologic formations downward. These are thought to be the result of the dissolution of deep-lying formations. This oil and other oil spots detected in core tests in the breccia pipe were studied and analyzed by the U.S. Geological Survey as part of the WIPP project [Evaluation of Breccia Pipes in Southeastern New Mexico and their Relation to the Waste Isolation Pilot Plant (WIPP) <u>Site</u>, U.S. Geological Survey (1982), attached as Exhibit 20]. This Report reached the following conclusions regarding the source of the oil:

"Minor amounts of oil-stained core from both WIPP 16 and WIPP 31, as well as oil seeps in the MCC drifts near Hill C, were analyzed to see if an answer could be found to account for the presence of the oil (Palacas and others, 1982). Gas chromatograph and geochemical analysis indicate that the three oils are related to the oil from wells to the north of the pipes taken from the Yates Formation. The Yates overlies the Captain reef on the backside of the reef. It is possible that oil from this formation migrated toward the area of the breccia pipes and either entered the rocks before collapse occurred or it was forcefully emplaced during collapse, being stratigraphically upward pushed by hydrostatic pressure as the water in the underlying void was forced upward by the infalling rocks. In WIPP 31, the oil stains were in rocks of Dewey Lake Red Beds and Rustler and Salado Formations consisting of siltstone, anhydrite, and dolomite fragments and a matrix of mud, recrystallized halite, and glauberite crystals. In WIPP 16, the oil stains were in the Rustler Formation in anhydrite above the Magenta Dolomite Member and in halite below the Culebra Dolomite Member. The oil seeping into the MCC mine appears to be coming from an early vertical fault about 43 M (140 ft.) from the edge of the breccia pipe." [Exhibit 20, p. 65].
Regardless of where it came from, it is clear that the oil migrated into the mine.

The oil seepage at the Lundberg Industries (old PCA mine) mine did not involve a breccia pipe. These oil seeps, however, were traced to an improperly plugged well in the Getty Field located about 700 feet away. Information on these oil seeps, which were discovered in 1962, is attached as Exhibit 21.

If oil will migrate the distances involved in these incidents, we shudder to think what methane or hydrogen sulfide under high pressure would have done. We know from the Rutledge studies in 1963 [Exhibit 3, App. D] that the clay seams in the Basin have a degree of permeability and will allow gases to migrate a distance of at least seven feet when the pressure is 50 psi [Exhibit 3, App. D, p. 64]. These clay seams are uniform throughout the Basin so if they become charged with high pressure gas, no one can say, without additional study, how far they will migrate.

## 4. Industry Experience With Cementing

Our own experience also makes us question whether any casing and cementing program, unless supplemented with additional safeguards, is adequate protection against the hazards we are dealing with. In 1980, for example, AMAX drilled a bore hole from the surface to the mine workings to be used for electrical supply cables. In attempting to cement the casing, the cement was lost both above and in the salt section through, we assume, clay seams and fractures in the salt zone. In

- 23 -

instances like this, we simply do not believe there is any reliable way to be certain that the voids and annulus of the casing are completely filled. Information on this bore hole is attached as Exhibit 22.

More recently, International Minerals and Chemical Corporation experienced similar difficulties in a grouting program to stop the migration of water. A summary of this experience is attached as Exhibit 23. If water at relatively low pressure can migrate as easily as occurred at IMCC, then we seriously question whether cementing programs can effectively prevent the migration of flammable gases under much higher pressures.

## 5. Corrosive Effects of Hydrogen Sulfide

Finally, we believe the well casing program, which has gone unchanged for over 30 years, needs to be reviewed in light of new developments to ensure that it offers state-of-the-art protection against the release of gases. Currently, R-111-A only requires new or used casing "in good condition" [Exhibit 13, pp. 3-5] without specifications concerning the ability of the casing to resist corrosion from hydrogen sulfide or withstand high pressures. The presence of hydrogen sulfide in the Basin has been known for years [See Exhibit 12, p. 9, testimony of S.J. Stanley] and was encountered during the core hole drilling by the U.S. Geological Survey in 1982 while investigating the breccia pipe and oil seeps at the MCC Mine [See Exhibit 19, p. 39] and along with high pressure (1500 psi)

- 24 -

resulted in a casing failure at the Washington Ranch Gas Storage Facility of El Paso Natural Gas Company. The effects of hydrogen sulfide on casing is well known and needs to be addressed because of its internal effect on well casing.

## V. Effects of Hazards from Oil and Gas Activities on the Potash Industry

The effects of these hazards on the Potash Industry are significant and far greater than they were when R-111-A was first adopted. In 1955, there were few safety requirements of economic consequences concerning flammable gases. Those in effect applied only to a few very gassy coal mines and were of no concern to the Potash Industry. However, that has all changed. As a direct result of the many mine disasters caused by flammable gases, significant changes in mine safety and health laws were made in 1959, 1969 and again in 1977. Each time the regulations became more stringent and the consequences of a gas encounter more severe. Today, the consequences are such that a single release of flammable gas into any one mine could destroy our Industry.

Under the Federal Mine Safety and Health Act, non-coal mines, like us, are considered non-gassy unless one of four events occur. One of these is the finding of a single air sample containing .25 percent methane or some other flammable gas. If such an event were to occur, we would be classified as

- 25 -

gassy and required to comply with about 100 additional regulations, all designed to prevent an explosion.

These additional regulations would require us to sink more shafts for ventilation; replace all underground equipment or modify it to explosion-proof condition; and replace most if not all of our electrical systems. In 1982, we estimated this would cost over \$80 million if all of the mines were forced to comply with these regulations.

This change in consequences, of course, has made us much more defensive on the drilling of oil and gas wells in the Basin. We do not see any change in that position unless R-111-A is revised to ensure that our Industry does not bear the risk and liability of a mishap while the Oil and Gas Industry receives the benefit of production.

These activities also affect us in other ways. Our operations, like all others, have assets. These assets are, in large part, our recoverable ore reserves. It is the value of these reserves that tell us whether it is economically possible to sink a shaft or continue mine operations. If an oil or gas operator wants to drill a well through these reserves, he is asking us to permanently forfeit some of our assets because once a well is drilled we cannot safely mine in close proximity to that casing regardless of whether it is producing or was a dry hole. The value of the ore lost will depend upon a number

- 26 -

of factors, including market price, but it is nevertheless a significant loss to us.

Such activities also impact our mine development. Under R-111-A, we are required to submit a mine development plan each year projecting where we will be mining during the next 3-5 These are supposedly used by the OCD in determining years. whether to allow or disallow a proposed well. However, in our Industry, there is simply no way to accurately predict where we will be mining next month, much less three years hence. If the demands for our product change, we may need a different grade or mix of ore and have to mine in a direction not shown by the annual mine plan. Copies of the mine development plan filed by IMCC in 1981 and a map updated to January 1, 1986, showing all mining through 1985, is attached as Exhibit 24 for reference. Thus, and for this reason, we are forced many times to protest a well to ensure that it does not interfere with the orderly but unpredictable development of our mine.

## VI. Factors that Must be Considered to Address Hazards

In addressing the hazards created by oil and gas drilling in the Potash Basin, we believe there are a number of factors that must be considered. Many of these are currently being done or in place, but others are the result of new technology and capabilities that did not exist when R-111-A was adopted.

- 27 -

## 1. Safety of Miners

We firmly believe, as stated in these comments, that the current provisions of R-111-A do not adequately protect our mines and miners from the hazards associated with oil and gas drilling in the Potash Basin. Each section of R-111-A should be reviewed to ensure that it does not encourage or allow development by either industry at the expense of safety. Currently, there is no notice requirement in R-111-A for anyone who may be affected by a proposed oil or gas well except a miner operator. We believe this should be broadened to include our miner representatives so that they, too, will be in a position to evaluate any potential hazards from future drilling activities.

## 2. Studies of Gas Migration to Determine Spacing

A spacing requirement between oil and gas activites and ore deposits must be developed and adopted to ensure the safety of miners. The hazards involved are simply too great to rely solely upon a casing and cementing program. Any spacing requirement must consider the possible migration of gases as well as the spacing required to avoid damage from mining subsidence.

### 3. Subsidence

Mining subsidence must, of course, be considered. It is well known that the extraction of ore from support pillars during second mining causes subsidence or a "sinking" of the

- 28 -

ground. The effects of this are well known by the OCD and, because of possible damage to well casing, preclude the drilling of any well at a surface location that will fall within a 45° angle thrown upward from where mining occurs or will occur.

## 4. Responsibility for Gas Releases

Once a determination is made on what spacing requirement is necessary to protect each industry from the other, we believe there should be a clear regulatory assignment of economic responsibility for any damage caused by one industry to the other. For example, if a well is drilled at a location determined by the OCD to be safe and we damage or destroy that by our mining activities, it will be our economic well responsibility to restore production or incur the liability for whatever loss is incurred. Similarly, if a well is drilled at a location determined to be safe by the OCD and thereafter releases hazardous gases into the strata which migrate into our underground workings, the oil or gas operator will be economically responsible for whatever additional costs or loss of assets we incur as a result of that release.

## 5. Identification of Ore Bodies and Barren Areas

Current procedures for identifying ore bodies and barren areas need to be improved to provide more guidance to both Industries. In many instances, commercial grade ore extends well beyond the boundaries of the R-111-A area and this is not

- 29 -

known to an oil and gas operator until a protest is filed. We believe the identification of these areas should be the shared responsibility of both the Industries and the OCD because of its obligation under New Mexico law to conserve those mineral resources.

## 6. Increased Use of State-of-the-Art Directional Drilling Technology

Increased use of directional drilling should be required. The technology available today virtually eliminates any technical limits on bottom hole displacement. Using this capability, wells could be drilled from locations sufficiently removed from ore deposits that the effects of the hazard would be greatly reduced. Any increase in costs, we believe, would be justified by the increased safety to miners.

## 7. Increased Cooperation Between the OCD and BLM

We believe that any real effort to address the hazards involved in oil and gas and potash production will require increased cooperation between the OCD and BLM. Because of the nature of the hazards involved, it is essential that whatever safety practices are adopted are applied equally without regard to whether the drilling is on state or federal property.

## 8. Increased Cooperation Between Industries

We would like to see increased cooperation between our two Industries to ensure that all developmental activities in the Basin are performed in a manner that does not endanger our

- 30 -

miners. This Study Committee is a good start, and we hope it will lead to a greater mutual understanding of the many issues involved.

## VII. CONCLUSION

For the reasons set forth in these comments, we believe that R-111-A is obsolete and must be revised. It is clearly inadequate under today's safety standards to protect our mines and miners from the hazards associated with oil and qas drilling activities. These deficiencies can be addressed in a number of ways, and we have suggested some alternatives in these comments. There are undoubtedly many others that will be identified during the work of this Committee. In the final analysis, however, we believe that any new regulations governing the drilling of oil and gas wells in the Basin must strike the balance between production and safety in favor of safety and not require one industry to assume the risk created by the other.

Respectfully submitted,

CHARLES C. HIGH, JR. Attorney for Carlsbad Potash Industry

1096L-5

POTASH IN 1983

i

The attached 2 pages reprinted from the Bureau of Mines Mineral Commodity Summaries--1984, provide the earliest estimates of 1983 data and activity highlights on Potash. Most of the estimates are based on 9 months data and are compared with prior years final data.

Prepared by the Division of Industrial Minerals, December 30, 1983.

8. Events, Trends, and Issues: Demand for potash in the United States increased about 1% in 1983 compared with that of 1982 but was still nearly 17% below that of 1981. Production in 1983 decreased about 27% compared with the 1982 level. The payment-in-kind program, low farm earnings, and high interest rates reduced demand for fertilizer. One domestic potash plant closed until potash prices rise significantly, while a near-surface brine operation closed temporarily because rain flooded its gathering trenches. Most other plants either shut down for long summer vacations and maintenance or operated on reduced work schedules.

Exports decreased about 33% while imports increased about 9% compared with those of 1982. Exports fell, primarily due to the strong U.S. dollar and the reduced levels of Brazilian, Indian, and Japanese imports. Significant quantities of Canadian potash were loaded at Thunder Bay, Ontario, for lake freightage to Burns Harbor, Ind.; Toledo, Ohio; and Baltimore, Md. Imaginative efforts by Canadian potash producers in reducing transportation costs to U.S. markets have increased their market share. The size of the market remaining for the domestic producers relative to their capacities has become a problem.

The U.S. Department of Labor, Mine Safety and Health Administration released its preproposal draft concerning "Metal-Nonmetal Standards, Section 21-Gassy Mines," which presented a fivelevel gassy mine categorization system. Category placement is by (1) the history and geology of the province and the mine; (2) the nature of the ore body and the host rock; and (3) the character of methane gas emission (if any). Under the old two-level standards, two Carlsbad, New Mexico, mines were under threat of being declared "gassy" and forced to convert to "permissible" technology and operations. The capital cost of this conversion could have put the mines out of business. Under the new standards, the potash mines probably would be rated at the lowest levels of gas presence, which would require small additional costs to the companies.

It is estimated that in 1984 domestic mine production of potash will be 1.7 million tons and U.S. apparent consumption will be 5.9 million tons. From a 1981 base, demand for potash is expected to increase at an average annual rate of 2.2% through 1990.

- 9. World Mine Production and Reserves: **Reserve Base** Production 1982 1983 e/ 1,784 1,300 300,000 United States Canada (sales) 5,196 5,500 45,000,000 1,750 France 1,823 60,000 2,500 Germany, Federal Republic of 2,500 600,000 Israel/Jordan 1,010 1,300 3/300,000 Italy 160 160 12,000 Spain 690 690 75,000 United Kingdom 240 280 75,000 Other Market Economy Countries 20 22 200,000 China 25 25 200,000 German Democratic Republic 3,500 3,500 1,000,000 9,000 U.S.S.R. 9,000 3,800,000 25,950 World Total (may be rounded) 26,000 51,600,000
- 10. World Resources: Estimated domestic potash resources total about 6 billion tons. Most of this lies between 6,000 and 10,000 feet deep, in a 1,200-square-mile area of Montana/North Dakota as an extension of the Williston Basin deposits in Saskatchewan. The Paradox Basin in Utah contains approximately 2 billion tons, mostly at depths of more than 4,000 feet. About two-thirds of the world's resources are located in Saskatchewan. Most of the North American resources are recoverable only by solution mining techniques because they are found at depths greater than 3,500 feet. Estimated world resources total about 250 billion tons. The potash deposits in the U.S.S.R. are the bulk of the Centrally Planned Economy countries' resources. Very large resources, about 10 billion tons and mostly carnallite, occur in Thailand. Significant resources occur in the German Democratic Republic and the Federal Republic of Germany.
- 11. Substitutes: There are no substitutes for potash as an essential plant nutrient.

January 1984

## $\frac{POTASH}{(Data in thousand metric tons K_0^0 equivalent)}$

1. Domestic Production and Use: The value of U.S. production of marketable potash, f.o.b. mine, in 1983 was about \$190 million. Potash production was centered in southeastern New Mexico, where six companies, operating six mines by conventional mining of bedded deposits, produced 87% of the U.S. total. One mine closed on January 24,1983, for an extended period of time due to low potash prices and to reduce inventories while several others closed for several months to reduce inventories. All other mines were operated at reduced levels. One mine in Utah recovered potash by solution mining underground and pumping it to the surface for solar evaporation and flotation. Two plants in Utah and one in California recovered potash from salt lakes or subsurface brines. Coproducts were boron compounds and salt cake from brines in California and salt, salt cake, and magnesium chloride brine from the Great Salt Lake in Utah. About 95% of the U.S. output was used directly in the fertilizer industry and about 57 was used in the chemical industry. Most potash was produced as potassium chloride (muriate of potash). Potassium sulfate and potassium magnesium sulfate, produced for special crops, comprised about one-sixth of the potash production. Potash was distributed by train, truck, and barge to warehouses, wholesalers, and retailers. Retailers sold both potash and potash blended with other fertilizers in dry or liquid forms for distribution over the fields in both spring and fall.

#### OF CARLSBAD POTASH DISTRICT

The denial of access to German sources of potash fertilizers during World War I was sufficient incentive to cause a nationwide search for a domestic source in our known bedded salt deposits such as in the Michigan, Paradox, Williston and Permian Basins. Early investigations by the U.S. Geological Survey favored the Permian Basin because the mineral polyhalite had been recognized over wide areas of southeast New Mexico and west Texas from cuttings recovered from holes drilled for oil, Hoots, 1925. The desire to find domestic sources was demonstrated by the enactment of Public Law 424 in 1926 which authorized a 5-year exploration program, including core-drilling, by the U.S. Geological Survey and U.S. Bureau of Mines. The government drilled a total of 24 widely spaced holes between 1927 and 1931, 13 in New Mexico, 10 in Texas and 1 in Utah. Simultaneously, private industry joined into the search, with geologists carefully examining cuttings from holes drilled for oil but penetrating salt on the way down. Fortunately, most of the drilling still was done with cable tools during the late 1920s which insured a saturated brine would build-up in the hole and thus retard dissolving soluble potash minerals.

Although it was the U.S. Geological Survey who initiated the potash exploration program, serendipity played its usual role in the discovery. Drill cuttings from the Snowden-McSweeney No. 1 McNutt wildcat provided the first evidence of commercial amounts of sylvite. The well was spudded on July 5, 1925, and reached its eventual total depth of 4416 feet on March 20, 1926. V.H. McNutt is credited with the identification of several significant intercepts of sylvite by examination of the cuttings. That serendipity played its role rests on these eventual revelations: 1) the hole was drilled for oil of which none was found, 2) the hole location was almost at the exact "center of gravity" of the numerous ore bodies now known in the district, 3) potassium mineralization was present in all 11 of the now accepted ore horizons, but 4) no potash mining has been done in the immediate vicinity of the hole because of the low grade in comparison with surrounding areas.

The American Potash Company was formed initially as a subsidiary of the Snowden-McSweeney Oil Company. A core-drilling program was commenced which immediately proved up reserves of sufficient size and grade to justify mine development a short distance west of the initial discovery. The holdings of the American Potash were transferred and reorganized into the U.S. Potash Company which in turn was a subsidiary of U.S. Borax. Mining commenced in 1931. The Potash Company of America opened a second mine in 1934. The capacities of these mines were steadily increased and still other companies opened new mines until there are now six companies working in the district (Fig. 1 and 2).

At present 3000 persons are directly employed by the Carlsbad potash industry with an annual payroll of \$60 million. While the potash industry is affected by national economic trends and faces stiff foreign competition, it has been one of the most stable industries in New Mexico.

#### STRATIGRAPHY

The Carlsbad district is located within a classical marine evaporite basin. The total thickness of evaporites ranges from 1000 feet in the

-2-

٤

MAP

ł

northern mines to as much as 3000 feet in the south. The potash deposits are restricted to thin lenses (4 to 8 feet) within this thick sequence of salt and anhydrite beds. The potash mining horizons occur in the upper portion of the evaporites; thus an "insulating" blanket of salt and anhydrite separates the potash mining levels from underlying sandstone and porous carbonate beds that contain oil and gas. The thickness of this insulating blanket is never less than 400 feet and may be as thick as 2500 feet. What will now follow is a more detailed description of the character and method of deposition of these evaporites that will fully explain the reason that potash mining horizons are completely isolated from entry of gases from underlying oil-gas reservoirs.

The potash deposits lie within a large Permian aged structural feature known as the Southern Permian Basin. The basin is of large areal extent, covering most of southeast New Mexico and west Texas. This basin, along with its ancestral structures, contains one of the most complete stratigraphic sections of the Permian to be found anywhere within the continental U.S. A generalized stratigraphic cross-section is presented in Figure 3. The entire section is in the order of 16,500 feet thick, two-thirds of which is of Permian age. The Permian is divisable into four series: Wolfcampian, Leonardian, Guadalupian, and Ochoan.

Note the postion reefs and carbonate banks on Figure 3. Throughout Guadalupian time a large reef commenced to grow which separated deep marine sedimentation on the south from shallow lagoonal deposition to the north. The back reef environment was ideal for the eventual formation of oil reservoirs.

Figure 3. Generalized geologic cross section from south to north through the vicinity of the Gnome site and the potash mines, Eddy and Lea Counties, New Mexico. By the close of Guadalupian time the Capitan Reef had reached a thickness of 1000 feet and formed a complete oval shaped barrier that cut off what is now called the Delaware Basin from the main Permian seas to the south. This barrier set the stage for formation of the Ochoan evaporites by a simple ocean drying process. Sediments could no longer pass through the reef into the basin, and pure beds of anhydrite and salt formed in a deep water environment. These deep water evaporites are called the given name of Castile Formation. Shales and carbonates continued to form behind the reef, but the environment rapidly became highly saline and organic life could no longer be sustained either in front of, over, or behind the reef.

ŧ

i

ŧ

ţ

ł

1

1

1

Marine waters invaded again after the close of Castile time. The conditions continued to be quite arid and halite and anhydrite precipitation continued, represented by the Salado Formation. The bed characteristics are such to indicate that this deposition was in shallow evaporating pans. The Salado evaporites are extensive; they cover most of the Permian Basin. At certain times, evaporation of marine waters continued to the extreme end point where all calcium and sodium had precipitated to form gypsum and halite. The residual bitterns became highly enriched in potassium and magnesium. These bitterns accumulated in restricted basins to be eventually precipitated as potash mineral deposits.

The Rustler Formation overlies the Salado. These beds contain dolomite, anhydrite and salt at the base which grade upward into clay and silt deposits. This sequence of deposition is interpreted as representing an initial transgression of marine waters, followed by evaporation. Then a

-7-

final regression of the sea occurred that allowed fluvial sediments (clay and silt) to cover and preserve the underlying evaporites. The fluvial beds are called the Dewey Lake Formation and represent the close of Permian time in this part of New Mexico.

1

ł

3

÷

1

ŧ

ą.

1

t

The Triassic is represented by red bed type deposits of sandstone, siltstone and conglomerate of the Santa Rosa Formation. These deposits rest on the Dewey Lake with only a moderate unconformity. The stratigraphic history is missing from the Triassic to the Late Tertiary Cretaceous rocks may have been present but if so, they were removed by erosion. The oldest beds now overlying the Santa Rosa are the gravel deposits of the Ogallala Formation. The Ogallala has been stripped in the eastern portion of the district by erosion associated with the present Pecos River drainage.

#### STRUCTURE

While major structures exist to the west (Guadalupe Mountain Uplift), the structural setting within the potash mining district is monotonously flat. Figure 4 is a north-south cross-section through the district. The undulations of the beds is due to the extreme vertical exaggeration used to compile the cross-section. The most prominent subsurface feature is the Capitan Reef, which separates the Delaware Basin from the Northern Shelf. Note that the deep marine evaporites of the Castile thin rapidly from the basin as they pass over the reef. On the other hand, the Salado is of fairly uniform thickness from basin onto the shelf. Therefore, the effect of the reef on sedimentation was limited to the period of time from its growth during the Guadalupian until the basin was filled

by the earlier Ochoan Castile Formation. The Salado, Rustler and Dewey Lake Formation appear to have been deposited in a broad and shallow tidal basin environment that has been little disturbed since, except for a gentle tilting to the east.

Two additional structures need to be mentioned. A Tertiary aged basaltic dike transects the mining district. The general trend of the dike is N. 50° E. The dike has been encountered in the IMCC Mine in the southwest and in the Ker-McGee Mine in the northwest. No offset of beds has been noticed, it is thin (2 to 6 feet), there are no associated fluids, and it has presented no difficulty to mining. The other type structures are solution collapsed chimneys. The origin is thought to be due to groundwaters within the underlying Capitan Reef having dissolved salt from the base of the Salado or due to collapse of caverns within the reef itself. One of these collapsed chimneys has been encountered in the Mississippi Mine, but it presented no obstacle to mining, other than destroying the ore bed within the actual breccia.

### DETAILED STRATIGRAPHY OF THE OCHOAN EVAPORITES

The Ochoan is divided into four formations; see Table 1. Figure 5 is a general stratigraphic column of the entire Ochoan along with an expanded section of the McNutt Member of the Salado Formation. The cyclical nature of deposition, commencing with mudstone at the base followed by anhydrite and finally salt, is much in evidence throughout the Salado. These rhythmic cycles, averaging 4 feet thick but may be as thick as 20 feet and as thin as less than one foot, are thought to be due to periodic

-10-

Table 1. Description of Ochoan Rock

|                                         | Red siltstone, sandstone and mudstone.<br>Thin lamination and small-scale cross<br>lamination common.                                                                                                                                                                                                                                                                |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | Mostly anhydrite with some salt. Con-<br>tains two dolomite layers, a basal sand-<br>stone, and several thin layers of clas-<br>tics. The two dolomite layers are nor-<br>mally aquifers in most of the eastern<br>part of the district, and halite has<br>been removed from the section and origina<br>anhydrite converted to gypsum.                               |
| Upper<br>500 ft.                        | Halite with regular but thin beds of<br>anhydrite and polyhalite. Clay seems<br>common at the base of the anhydrite-poly-<br>halite seams. Suberosion by groundwaters<br>has removed much of this member in the<br>eastern part of the district.                                                                                                                     |
| McNutt<br>300-500<br>ft.                | The overall character is identical to<br>the Upper and Lower Members. The impor-<br>tant exception is that sylvite and<br>Langbeinite occur as thin (1 to 10<br>feet) beds within this unit.                                                                                                                                                                         |
| Lower<br>400-1500<br>ft.                | Identical in lithology to the Upper Mem-<br>ber except that halite units are thicker<br>and purer.                                                                                                                                                                                                                                                                   |
| 0-1500<br>ft.                           | This formation is present only in the<br>Delaware Basin, i.e. south of the Capitan<br>Reef. Near the reef the section is almost<br>totally anhydrite. South of the reef it<br>consists of equal portions of salt and<br>anhydrite in thick beds. The halite is<br>very pure. The anhydrite is "banded" with<br>thin alternating layers of anhydrite and<br>dolomite. |
| ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~ |                                                                                                                                                                                                                                                                                                                                                                      |

A uniform stratigraphic code has been developed by the U.S. Geological Survey to describe the Salado. (Smith, 1938, and Jones, et al., 1960). The code designates 43 "marker bed" horizons commencing with 100 at the top down to 143 which lies just above the Cowden Anhydrite. The Cowden and two other beds (Vaca Triste and Union) retain formal names to agree with prior usage in southeast New Mexico. The base of the Salado is normally picked at the top of the first massive banded anhydrite in the Castile. Marker beds consist of a thin seam of mudstone at the base followed by a variable thickness of anhydrite. Frequently the anhydrite has been either partially or completely replaced by polyhalite.

Commercial quantities of potash are limited to the McNutt Member of the Salado. The McNutt being defined as the interval from Marker Bed 126 up to the Vaca Triste, a mudstone-sandstone bed. Eleven ore horizons normally are recognized within the McNutt commencing with the First Ore Zone which occurs between Marker Beds 126 and 125 up to Eleventh located immediately above Marker Bed 117. Thus Marker Beds are numbered sequentially downward, and Ore Zones are numbered sequentially upward. Two other potash rich beds are known that occur above the McNutt, but commercial amounts of potash mineralization are not known in them.

The eleven ore zones are consistent in their stratigraphic relationship between marker beds; however, the thickness and mineralogy is quite variable. Mineral suites and ore zone characteristics are given in Tables 2 and 3.

-13-

Table 2. Evaporite minerals of the Carlsbad district. Only sylvite and lanbeinite are ore minerals at the present time. The hydrated potassium minerals are not amenable to existing concentration methods.

| Mineral        | Formula                                                                                         | Equivalent Percent |        |                    |                                   |

Ore zones exhibit considerable effects of diagenetic processes. Jones (1954) divided potassic mineral occurrences as:

(1) Accessory minerals

L

3

1

ş

7

ŧ

.

i

i

- (2) Stratified deposits in sulfate strata
- (3) Bedded deposits in mixed halite-clastic strata
- (4) Veins or lens deposits that have replaced or displaced the strata

The accessory minerals category includes widespread but very low grade occurrences of soluble potassium minerals in halite beds. The stratified deposits in sulfate strata are those original anhydrite marker beds which have been at least partially replaced by polyhalite. The bedded deposits are what constitute the true ore zones of the Carlsbad district. The spacial relationship between the ore zones and the more widely distributed polyhalite and accessory mineral occurrences of potash mineralization is observed in Figure 5. The polyhalite and accessory mineral occurrences can be considered as halos. Veins or lens of pure or mixed assemblages of potassium minerals occur, but in and adjacent to ore their contribution to minable reserves is quite small.

While ore zones remain in consistent stratigraphic positions, the original sedimentary features of the beds is mostly obliterated by authigenesis and recrystallization processes that followed original deposition. While these processes caused the formation of commercial deposits in some localities, it is also apparent that late moving fluids, unsaturated in potassium, destroyed what would have constituted ore.

#### SOURCE OF LIQUIDS AND GASES IN THE EVAPORITES

It is well established that liquids (as saturated brine) and gas (mostly nitrogen with minor amounts of methane) are associated with the Salado Formation. These fluids occur in three forms.

#### Negative Crystals in Halite

1

j

1

į.

1

ţ

1

1

4

۶.

ł.

A negative crystal is simply a void within a halite crystal. The voids are most commonly entirely filled with liquid but occassionally include a gas bubble. The term fluid inclusion is also used to describe negative crystals. Negative crystals are common to essentially all halite deposits, i.e., they are not unique to the Salado. The size of the fluid inclusions range from microscopic up to a centimeter across. The normal shape is cubic but rounded shapes are also present. In the Salado the average size is less than 5 microns for the cubic crystals up to 100 microns for the rounded ones. Brine within negative crystals account for 0.5% by weight of typical halite. Gases associated with the brine is almost insignificant, accounting for only about 1% of the brine or 0.005% of halite.

#### Brine Absorbed in Clay Within Halite

Some of the halite or mixed halite-sylvite beds contain several percent clay. These clays can normally be expected to contain around 25% moisture. Some of the ores mined contain as much as 5% clay; therefore, such high clay ore will contain about 1% salt saturated water. Some gas may be occluded on the clay, but the amount must be small because none has been measured to date. Brine and Gas Associated with Clay Seams at the Base of Marker Beds This is by far the most common occurrence of liquids and gases in the Salado. The brines are saturated in potassium, magnesium and sodium. The prevalent anions are chloride and sulfate. This chemistry is indicative of residual bittern fluid associated with the original formation of the potash deposits. The gas components are nitrogen along with minor amounts of methane. The source of the gas is from original atmospheric air that was either in solution with the original seawater or was trapped under salt-anhydrite crusts formed on the surface of the evaporation pans. That oxygen is totally absent is easily explained by the high activity of that gas -- it would react with other elements to form stable oxide minerals such as hematite.

## GEOLOGIC REASONS THAT BRINE AND GAS WITHIN THE SALADO ARE ISOLATED FROM FLUIDS EITHER ABOVE OR BELOW

Halite has the well known behavior of behaving plastically under pressure. Petrofabric analysis along with modern day observation of halite being deposited in evaporation basins indicate that loosely packed crystals form within saturated brine pools. Continued burial forces the brine upward so that closer packing is achieved. On continued burial the halite crystals become completely plastic and all brine is ejected. The only exception being those fluids trapped in negative crystals at the time of crystallization. Thus halite becomes a true solid and possesses no porosity (except for brine filled negative crystals) and therefore no permeability. Permeability tests performed on

-18-
salt cores either yield results that are beneath the measurement capability of the test apparatus or if measureable can be accounted for by fractures induced into the sample.

Other evidence of impermeability of halite lies in the fact that brine and gases trapped in the clay seams at the base of the marker beds have remained in position since deposition. The approximate age of the Ochoan evaporites is 230 million years. That the brine and gas remain in position is due to the halite immediately under and overlying the fluid bearing strata.

The McNutt Member is underlain by 400 to as much as 1500 feet of halite of the Lower Member of the Salado. Thus, the potash mining horizons are protected not only by halite immediately above and below the mining horizons but by an extra 400 to 1500 feet of halite provides additional impermeable barrier between the mining levels and any oil-gas horizons located in Guadalupian strata below. Evidence that these lower halites are impermeable is proven by the fact the brine and gas, which are under high pressure, remain in position and have not escaped upward to be vented to the atmosphere. They have been prevented from doing so by the overlying Upper Member of the Salado. The thickness of the Upper Member ranges from 100 to 500 feet over most of the mining district, i.e. less than what is below.

# PROBABLE SOURCE OF HYDROCARBONS IN THE SALADO

Hydrocarbons, mostly as simple methane, are present in trace amounts in the Salado Formation. Methane has been detected in both the gases from the clay seams at the base of the marker beds and in fluid inclusions

-19-

within halite. The richest concentrations are in the clay seam gas where it reaches as high as 6.37% methane. In all cases, the balance of the gas mixture is inert, consisting of nitrogen in the mud seams and carbon dioxide and nitrogen in fluid inclusions. Oxygen is not present; therefore the methane can not be considered as explosive. It must be remembered that gases released from drill holes diffuse into the mine atmosphere. The methane content thus decreases and never enriches. To do otherwise is contrary to the laws of gas dynamics.

ł

ŧ

ŧ

ĩ

We have argued that the halite beds that separate the potash mining zones from underlying oil-gas reservoirs are impermeable. Therefore, we must now explain the presence of methane in marine evaporites which were deposited from highly saline solutions which supposedly would not support any form of life. The answer lies in the cyclical nature of deposition of the evaporites. As previously described the cycle commences with a thin layer of clay covered by a thicker but still thin sheath of anhydrite followed by a much thicker bed of halite. The lower portion of the halite is normally purer (freer of clay) than the upper portion. This depositional cycle is interpreted as follows: (1) the clay seamlet represents an original drying and erosional surface at the top of the underlying halite. Clay minerals tend to concentrate at the surface. (2) Seawater re-entered the area causing additional solution of the underlying halite. Clay build up continues by settling of fine particles carried in by the seawater. (3) Evaporation recommences with first aragonite (CaCO<sub>3</sub>) and then gypsum (CaSO<sub>4</sub> $^{\circ}H_{2}O$ ) being deposited. The former will eventually be converted to dolomite  $(Mg,CaCO_3)$  and the latter to anhydrite  $(CaSO_4)$  by diagenitic processes. Some of the thicker marker beds are banded representing several cyclets

-20-

of aragonite and gypsum deposition. These are interpreted as refreshing of the seawater in some sort of periodic manner, perhaps seasonal. (4) Halite commences to crystallize. The original seawater becomes highly concentrated by evaporation. All of the calcium has been removed by the formation of aragonite and gypsum. (5) Drying continues with the formation of additional halite. The surface must be quite dry at this stage and blowing winds and occasional rainfalls on nearby above tidal surface deposits tend to add more detrital material to the evaporation pan. Therefore, more clay begins to be deposited along with the halite. (6) The evaporation cycle is complete setting the stage for the next cycle.

i

1

ŧ

ţ

1

3

3

ł

A reasonable estimate is that a quarter of a thousand of these cycles occurred during the deposition of the Salado Formation. The thickest of these cycles produced the several inch to several feet thickness of anhydrite which constitute the 45 marker beds now used to map stratigraphic position within the Salado Formation.

Marine organic life could exist at one period of time during the depositional cycle. That is during stage (2). Marine waters are assumed to reenter the area, albeit much more saline than the open sea. Algal and other microscopic organisms could exist. The modern analogy is algal "mats" observed in sabkha environments. Higher order organisms could not be present because no recognizable fossils have been identified in the Salado. The algae is the probable source of methane. Organic acids, the primodial form of heavier hydrocarbons, could be produced from other microorganisms. The assumption that this organic material existed under aerobic conditions is verified by the fact that the

-21-

gases now present in the Salado are nitrogen rich. Atmospheric oxygen was either consumed by the organisms themselves or later reacted with metallic ions to form stable oxides.

ļ

i

ł

ŧ

ł

ł

1

ł

The gases associated with the fluid inclusions is probably similar except that conditions may have been anaerobic. Oxygen deficiency is indicated because trace amounts of H2S are present and organic matter appears as organic acids rather than as methane. Inert gases, nitrogen and  $CO_2$ , are by far the most common constituents of gases within the fluid inclusions. The combined percentage of  $N_2$  and  $CO_2$  is never less than 90% and the highest methane analysis of samples tested did not exceed 0.5%. (Such a mixture is not explosive.) The gas composition of fluid inclusions in halite is considered to be in agreement with crystal formation under shallow subaqueous conditions. The high preponderance of nitrogen and carbon dioxide is explained by the soluability of those gases in brine. H<sub>2</sub>S, methane and organic acid in trace amounts is attributed to the decay of organic matter that was either able to survive under highly saline conditions or that was transported in by wave action or winds. The total amount of gas present in fluid inclusions is minute, accounting for only few tens parts per million by weight of the halite. Methane accounts for only 0.5% of these gases; or less than 1 ppm in halite.

### GEOCHEMICAL SAMPLE EVIDENCE THAT SUPPORT THE CONCLUSIONS THAT BRINE AND GASES CONTAINED IN THE SALADO ARE INDIGENOUS TO THE FORMATION

We have collected gas samples from relief holes drilled in the roof at 5 of the 6 active mines in the district. Twelve gas samples were collected in all. For reliability, seven samples were analyzed in a commercial

-22-

laboratory in Hobbs and five were analyzed by a State supported research laboratory. Not only did these two laboratory produce compatible results but overall results are in excellent agreement with results obtained by the U.S. Bureau of Mines which sampled the same mines in 1964. A summary of results is shown in Table 4.

ţ

ā,

ŧ

1

1

ì

Emphasis needs to be placed on the fact that our 12 samples and the 14 samples taken by the U.S. Bureau of Mines were all taken several feet up into relief holes. Therefore, the sample results are representative of the composition of the gas <u>in situ</u> and before being diluted with mine atmosphere. We took the normal precaution of using hand held methanometers to monitor the mine atmosphere while samples were being collected. In no case was a measurable amount of methane detected eventhough we were in the immediate vicinity of blowing holes.

The sample results indicate a consistent relationship. The gases associated with the base of the marker beds are nitrogen rich. The only other constitutents are methane along with even lesser amounts heavier hydrocarbon gases such as ethane.

The gases associated with fluid inclusions were also sampled. This was done by collecting run of the mine ore from all six of the active mines. To our knowledge this is the first time this has been done for Carlsbad potash ore. The only other fluid inclusion geochemical study that has been done is that by Sandia National Laboratories on core samples taken from the lower Salado and Castile Formation at the Waste Isolation Pilot Plant site south of the mining district, Powers, et al., 1978.

fFrom Rutledge, et al., 1964

The samples we took were analyzed by Dr. David Norman at N.M. Institute of Mining and Technology. The procedure he used is quite experimental but well suited for the specific task. The samples were first crushed with a clean hammer and 2 to 4 mm grains of ore were hand-picked. About 5 grams of sample were then placed in a cleaned quartz tube. The tube was then placed on a vacuum line and heated to 125°C. The purpose of this was to drive off all water of hydration. The temperature was then raised to 350°C. At this higher temperature the fluid inclusions ruptured, liberating both the enclosed brine (converted to water vapor) and gases. These gases were then passed through a mass spectrograph for analysis.

| 5        | 86.4            | 6.1            | 0.0             | 3.4  | 3.9              | 0.2           |
| 10       | 73.9            | 9.1            | 1.2             | 15.3 | 0.5              | 0.0           |
| Average  | 65.4            | 26.3           | 0.02            | 6.8  | 1.1              | 0.4           |

The results are comparable with gases associated with clays seams at the base of marker beds with these exceptions.

- 1. Inert gases consist of both  $CO_2$  and  $N_2$  in contrast to simply  $N_2$  in clay seams.  $CO_2$  is normally dominant. The average total of inert gases  $(CO_2 + N_2) = 91.7\%$ .
- 2. Methane is present only in trace amounts. Heavier hydrocarbons, mostly as organic acids, averages about 6.8%. These hydrocarbons may represent original organic matter that has only been partially decomposed.

-25-

3.  $H_2S$  is present which is indicative of an anaerobic condition at the time of formation of the fluid inclusions.

ł

ł

i

ŧ

ŧ

:

ł

ł

1

2...

L

۰.

4. The total weight percentage of fluid inclusions amounts to only 10 to 100 ppm of the ore. A ton of ore that was totally crushed would liberate only about one cubic feet of gas of which >90% would be inert.

The principal difference between the gases associated with fluid inclusions in contrast to those associated with clay seams is substitution of high molecular weight hydrocarbons and  $H_2S$  for simple methane and the partial substitution of  $CO_2$  for  $N_2$ . We tentatively conclude that conditions were anaerobic at the time of formation of the fluid inclusions. Atmospheric oxygen was totally used in partial conversion of organic matter to  $CO_2$ . The important similarity is that the bulk of both gases are inert, consisting of either just  $N_2$  or a mixture of  $N_2$ and  $CO_2$ . These gases were probably derived for the earths atmosphere.

In Figure 5 we compare the compositions of the clay seam and fluid inclusion gases with natural gases associated with known oil-gas producing areas near the potash mines. For this comparison we have used a three component diagram because the gases can be considered as a mixture of methane, heavier hydrocarbons and inert gas. The inert constitutent can be nitrogen or a mixture of nitrogen plus carbon dioxide. In order to more fully explain a three component diagram consider a gas that contains equal proportions of all three gases, e.g. 1/3 methane, 1/3 heavier hydrocarbons and 1/3 nitrogen. Such a gas would plot in the exact center of the triangle. On the other hand a gas that contains 100% methane would plot at the CH<sub>4</sub> apex.

-26-

Note that the compositions are distinctly different. The Guadalupian oil-gas reservoirs contain a mixture of methane and heavier gases such as ethane. Pennsylvanian gas reservoirs are mostly simple methane. In contrast, the clay seam and fluid inclusion gases are mostly inert. Trace amounts of methane are present in the clay seams. The balance is  $N_2$ . The fluid inclusion gas is mostly a mixture of  $CO_2$  and  $N_2$ .  $H_2S$  is present in trace amounts and probably represents the only other gas phase. Heavier hydrocarbons are present in minor amounts but not in the form of light gases such as methane, ethane, etc.

We have also collected samples of brine that issue from relief holes drilled above the potash mining horizons. These waters are completely saturated in K, Mg and Na salts and sulfates. We believe that these brines are representative of original bitterns associated with the deposition of the McNutt Member of the Salado. The composition of these waters is presented in Figure 6. A three component diagram of Mg-K<sub>2</sub>-SO<sub>4</sub> is used because all Permian waters have a common constituent of halite (NaCl). There are two principal aquifers near the potash mines, the Rustler above an the Capitan Reef below. Average composition of these aquifer waters is also shown on the Mg-K<sub>2</sub>-SO<sub>4</sub> plot to illustrate the distinctive characteristics of the saturated brines associated with clay seams.

In conclusion, the results of geochemical sample analysis indicate that the gases associated with clay seams at the base of marker beds near the ore beds and the gases contained within fluid inclusions in the actual ore beds consist of inert gases with only trace amounts of methane and  $H_2S$ . The composition is compatible with original

-27-

FIGURE 6 COMPARISON OF GAS SAMPLE ANALYSIS

atmospheric air being trapped into the evaporites at the time of their formation. That these gases have remained trapped in position since their original formation more than 200 million years ago is proof that the beds over and underlying the potash beds are impermeable. In addition, the brine waters associated with the clay seams is typical of bittern waters to be expected adjacent to potash deposits.

### COMPARISON OF THE CARLSBAD POTASH DISTRICT WITH OTHER DISTRICTS WHICH MINE EVAPORITE MINERALS

The Carlsbad Potash Mining District is distinctive from other evaporite mining districts in several aspects. First, the structural setting is simple. Beds dip no more than 2 degrees. While small faults have been observed they are few and limited to minor slippage due to local salt flowage. Anticlinal structures are absent. Sudden thickening or thinning of halite beds between markers beds has not been observed anywhere in the district. Salt flowage has been detected in the Castile Formation which underlies the Salado. Where observed these structures reduce to broad but low aptitude flextures in the Salado.

Second, the potash ore beds are contained in the middle of a thick section of rock salt. Ore is limited to the McNutt Member of the Salado. The Lower Member of the Salado provides from 400 to 1,500 feet of impermeable salt between the deepest mining levels and the shallowest oilgas reservoirs. No evidence of explosive amounts of methane gas has been detected in the course of drilling thousands of pressure relief holes in the Carlsbad District.

-30-

While we do not claim to be expert on other mining districts we can make the following comparisons.

#### Salt Domes of the Gulf Coast

1

ŧ

3

1

ż

7

1

Ŧ,

Ł

1.....

Salt domes are diapiric structures. The underlying Louanne Salt has pierced upward through weakly consolidated sandstones and shales. Oil and gas deposits are common to the flanks of these domes. It is only to be expected that methane gas can become entrained in the salt during its upward movement. These gases are methane rich in contrast to the inert gases associated with the Salado Formation.

#### Trona Deposits in Wyoming

Evaporites of the Green River Formation are lacustrine rather than marine. Oil shale beds are intercalated with the trona. The environment during deposition was one that supported abundant aquatic life in contrast to marine evaporties.

#### Potash at Cane Creek, Utah

The potash deposits are contained in marine evaporites similar to those of Carlsbad. However, there are two important differences. First, the individual evaporite beds are thinner. Marine black shales are present at regular intervals throughout the salt formations. These shale beds contain oil and gas reservoirs. Second, the potash deposits are highly deformed due to a large salt anticline. Thus the potash deposits at Cane Creek are somewhat analogous to the salt diapirs on the Gulf Coast. Methane gas is common and analysis has shown that the in situ concentration is 51.4% CH<sub>4</sub>, 21.2% ethane-pentane, and only 27.4% nitrogencarbon dioxide. Such gas is defintely explosive when mixed with normal

-31-

air. The gases in the Salado never contain more to 6.37% hydrocarbon gases and can never be considered explosive when mixed with normal air.

Environmental Evaluation Group Environmental Improvement Division Health and Environment Department P. O. Box 968 Santa Fe, New Mexico 87504

March 1984

The purpose of the Environmental Evaluation Group (EEG) is to conduct an independent technical evaluation of the potential radiation exposure to people from the proposed Federal radioactive Waste Isolation Pilot Plant (WIPP) near Carlsbad, in order to protect the public health and safety and ensure that there is minimal environmental degradation. The EEG is part of the Environmental Improvement Division, a component of the New Mexico Health and Environment Department -- the agency charged with the primary responsibility for protecting the health of the citizens of New Mexico.

The Group is neither a proponent nor an opponent of WIPP.

۰.

4

Analyses are conducted of available data concerning the proposed site, the design of the repository, its planned operation, and its long-term stability. These analyses include assessments of reports issued by the U.S. Department of Energy (DOE) and its contractors, other Federal agencies and organizations, as they relate to the potential health, safety and environmental impacts from WIPP.

i

The project is funded entirely by the U.S. Department of Energy through Contract DE-ACO4-79AL10752 with the New Mexico Health and Environment Department.

# INTRODUCTION

The impetus for this study was provided by a recent series of incidents at the Kerr-McGee mine near Carlsbad, New Mexico. On December 13, 1983, a miner operating a continuous mining machine apparently hit a pocket of trapped, pressurized gas. The sudden release of pressure from this gas pocket caused the gas to expand. This resulted in dislodging of rock and debris and loose fixtures on the mining machine. According to a preliminary investigation by MSHA, "The operator of the continuous miner was apparently killed as a result of being struck by a light fixture which had been torn loose from the continuous miner and hurled back into the victim's face." (See Appendix A, p. 34.) Two more incidents, fortunately non-fatal, within a 5 week period in the same mine have resulted in a concern about the possibility of the occurrence of such blowouts in the WIPP excavations. The blowouts occurred 9 miles north of the center of the WIPP repository.

U. S. Mine Safety and Health Administration (MSHA) and N. M. Inspector of Mines Department are investigating the Kerr-McGee blowouts. Officials of the Kerr-McGee mine are conducting their own investigations with the help of consultants of the causes of these occurrences and to make the mining operations safer. This study (EEG-25) uses the reported encounters of gas in the potash mines as well as the studies related to the WIPP project as valuable information to reach some tentative conclusions about the possibility of such a hazard existing at the WIPP excavations. The conclusions of this study do not relate specifically to the safety conditions at any given mine and make no judgements about incidents in the mines.

Factual information provided by the officials of the Kerr-McGee mine, N. M. Inspector of Mines and U. S. Mine Safety and Health Administration (MSHA), is gratefully acknowledged.

### GEOLOGY OF THE SALADO FORMATION

The WIPP site and all the potash mines in the vicinity are situated in the Delaware Basin in Southeastern New Mexico. The Salado Formation is a part of about 10,000 ft of sediments deposited under marine conditions in this basin during the Permian period (>225 million years ago). Initially deposition in the basin was bounded by the Capitan Reef. By late Permian, the basin had filled and the saline water spilled over to the north and east covering a large area now known as the Permian Basin. Evaporation at the surface of this shallow sea under arid conditions resulted in the precipitation of salts, mainly halite which accumulated over a period of time. The formation resulting from this process is called the Salado.

The Salado Formation varies in thickness but at the WIPP site and the potash mines, it is about 2000 ft thick. The Salado consists mainly of Halite (NaCl) and other salts including polyhalite  $[k_2Ca_2Mg (SO_4)_4 \cdot 2H_2O]$ , glauberite  $(Na_2SO_4 \cdot CaSO_4)$ , sylvite (KCl), Kainite (KCl  $\cdot MgSO_4 \cdot 3H_2O$ ) Carnallite  $(KCl \cdot MgCl_2 \cdot 6H_2O)$ , Langbeinite  $[K_2Mg_2 (SO_4)_3]$  and kieserite  $(MgSO_4 \cdot H_2O)$  as well as layers of clastic rocks and anhydrite. Beds locally rich in potassium minerals, primarily sylvite, carnallite and langbeinite, are mined from the McNutt Potash Zone located in the middle part of the Salado Formation. Other than the presence of potassium and magnesium rich minerals, the McNutt zone is similar in all other aspects to the rest of the Salado.

Using the remarkable continuity of individual beds in the Salado, the U. S. Geological Survey (Jones, 1960, 1973) has developed a system of identifing the stratigraphic location within the formation by designating 43 individual seams of anhydrite and polyhalite as numbered "marker beds." The first continuously identifiable bed of polyhalite, 120 feet below the top of Salado (at the WIPP site), is designated MB 101. The lowest marker bed (MB 144) consists of a bed of anhydrite in the lower part of the formation, 336 feet above the base of Salado at the WIPP site center. The proposed repository for WIPP is located between M.B. 138 and M.B. 139 in the lower part of Salado (Fig. 1).

Thousands of feet of drill cores and geophysical logs of boreholes in the northern Delaware Basin have been closely examined and correlated in connection with the site selection and characterization for the WIPP project. This study

Figure 1. Details of the stratigraphy of the Salado Formation showing the locations of the marker beds, ore zones and the WIPP repository. P = Polyhalite, A = Anhydrite

has shown that the deposition of the Salado Formation followed a cyclic pattern (Powers, et al, 1978). Each cycle consists of a layer of clay at the base followed by anhydrite or polyhalite and halite. The halite becomes more argillaceous as one proceeds upward. The cycle is finally capped by claystone and another cycle commences. This sequence is repeated several times as one studies the formation from the bottom to the top. The clay layers are thought to result from dissolution of clayey halite by inflowing sea water and thus each cycle probably represents a fresh influx of sea water in the evaporating pan. The beds of anhydrite (CaSO<sub>4</sub>) and thick deposits of halite (NaCl) represent long periods of evaporation from a progressively concentrated sea water under very arid conditions. Rock salt constitutes about 85-90 percent of the Salado Formation.

· .

i

Jones (1973) has provided a detailed study of the lithology of the Salado formation. According to him, the entire Salado Formation basically consists of alternating thick seams of rock salt and thinner seams of anhydrite and polyhalite. In this manner, the McNutt potash zone is very similar to the upper and the lower Salado. The potassic minerals at best comprise only 3 to 5 percent of the McNutt zone in the most potassium-rich sections of the northern Delaware Basin.

Figure 1 shows the details of the Salado stratigraphy as observed in borehole ERDA-9 at the center of the WIPP site. Locations of several important marker beds, the 11 ore zones within the McNutt potash member and the WIPP repository horizon are shown.

#### PHYSICAL CHARACTERISTICS OF GAS OCCURRENCE

Existence of gas pockets is a common feature of the evaporite deposits. In the potash mines of the Delaware Basin minor "poofs" of gas outburst is a common phenomenon. Several large blowouts have been reported from the potash mines, some of which have resulted in fatalities. Table 1 summarizes the reported incidents of gas blowouts in the potash mines near WIPP during the past 10 years. The incidents have been reported from (1) Kerr-McGee mine located 9 miles north of WIPP, (2) Duvall-Nash Draw mine located five miles west of WIPP and (3) Eddy mine of the National Potash Co., located 17 miles northwest of WIPP. Figure 2 shows the locations of these mines and the WIPP site. The following is a description of the reported incidents in the three mines.

#### Kerr-McGee Potash Mine - 1983, 84

The approximate boundary of the Kerr-McGee Chemical Corporation mine is shown in Figure 2. The author visited the mine on February 1, 1984.

The first of the three most recent reported incidents in this mine occurred on December 13, 1983 at 4:27 a.m. The mine level is in ore zone #10 (see Fig. 1) approximately 1600 ft below the ground level. The incident occurred in Area 169 in the southern part of the mine (Fig. 2). Figure 3 shows the exact location of the blowout.

A continuous mining machine was being used to cut the 6 ft high and 27 ft wide room. The mining was heading south when a gas outburst occurred in the upper right side of the indented working face. An estimated 8 tons of ore was dislodged out as a result of the outburst. Figure 4 is a photograph of the 9 ft long, 5 ft high and 2.5 ft deep cavity formed as a result of this outburst. Large boulders, weighing up to 500 lbs. were ejected up to 60 feet from the mine face. The operator of the continuous miner was killed and a shuttle car operator who was standing near his machine behind the continuous miner was injured by flying rock pieces. The blowout left an open fracture 1/4" to 1/2" wide, oriented S58°E. This fracture can be seen across the 27 ft wide room along the back (ceiling) and 2 ft down from the back in the eastern wall of Room 1 (Figures 5 and 6). Air samples from the open fissure

Fig. 2. | The mining machine was found 25 ft away from<br>the face where blowout occurred. Estimated<br>15 tons of ore was dislodged. A cavity about<br>60 ft <sup>3</sup> in volume was formed. Vertical frac-<br>ture trending 122°. One fatality. Figs. 2<br>and 3. MSHA report dated $1/16/84$ (App. A). | MESA (Precursor of MSHA) Report dated 4/7/76<br>(App. B). Roof fall (48'x32'x5'), 180 tons of<br>material, caused by trapped qases above the<br>roof. One fatality due to suffocation. | State Inspector of Mines report dated 11/27/74<br>(App. C). Roof fall with strong sudden air-<br>blast. One serious injury and seven lost-time<br>injuries. | State Inspector of Mines reports dated $4/18/74$ , $2/25/74$ , & $12/20/73$ , (App. C). Release of trapped gases with a floor break on $12/16/73$ . One sample from a floor bleeder contained $12\%$ oxygen and $16\%$ methane. On $2/24/74$ , an area of bottom approx. 230 ft x 230 ft fell 30 to 40 ft down after release of gas. A section of roof, 6 to 8 ft thick also fell near the center of the area of floor fall. |

Location of the WIPP site and potash mines where gas blowouts have been documented.

Figure 3. Detailed layout of Area 169 at the Kerr-McGee mine where the gas blowouts of 12.13.1983 and 1.23.1984 occurred. The orientation of fractures is shown. The fracture at A resulted from a previous blowout. (See Fig. 2 for location within the mine)

Figure 4. The location of 12.13.1983 blowout showing the cavity (9ft x 5ft x 2.5ft) formed and the vertical fracture trending 122° in Room 1, Area 169, Kerr-McGee mine (See Fig. 3 for location).

Figure 6. Fracture aligned 122° (N58°W, S88°E) in the back (ceiling) of the 12·13·1983 gas blowout in the Kerr-McGee mine. Picture looking SE in Room 1, Area 169 (See Fig. 3 for location).
within the blowout cavity taken by MSHA investigators on December 14, 1983 were analyzed to contain 89% nitrogen, 8% or less oxygen and from 3 to 6% methane. A report by Cavanaugh and Davidson dated January 16, 1984 provides details of this incident (App. A).

The second blowout in the Kerr-McGee mine occurred in Area 160 about 2 miles northwest of the first incident, on December 19, 1983. The outburst has left a vertical fracture trending 125° (N 65° W, S 65° E). The room at this location has been excavated to 12 ft above the floor to expose the fracture. About 8 ft above the floor, the fracture has been laterally displaced about 6 inches along a horizontal clay seam (Fig. 7).

The third of this series of gas blowouts in the Kerr-McGee mine occurred on January 23, 1984 at 4:50 p.m. at the same level and about 500 ft southeast of the December 13 blowout (Fig. 3). The operator of the continuous miner had started excavating in the face with the continuous cutter. There was a loud sound and debris started flying from the mining face near the cutter. The 50 ton continuous mining machine was knocked back about 2 feet as a result of the outburst and the operator was injured by flying debris. The mine personnel attribute the lack of a serious injury or fatality in this case to the protective metal grating which had been installed on the mining machine after the first two incidents (Fig. 8). An estimated 2 tons of rock was dislodged out of the cavity caused by this blowout. An open vertical fracture trending 110° (N 70° W, S 70° E) has been left in the face from which the gas escaped (Fig. 9). There are unconfirmed accounts of two more blowouts in the Kerr-McGee mine during February and March, 1984.

#### Duvall Nash Draw Mine - 1976

The Duvall-Nash Draw mine is located about 5 miles west of the WIPP site. The Sylvite level is only about 900 ft below the ground surface because of removal of rocks overlying the Salado in Nash Draw. A large roof-fall involving an estimated 180 tons of rock occurred at the sylvite level of this mine in early 1976. A report by Ellickson dated 4/7/76 provides the details of this incident (App. B). The investigation concluded that the roof-fall was caused by release of gases trapped above the roof. While examining the buried mining machine sometime after the roof-fall, the shift foreman died presumably of suffocation due to lack of oxygen.

۱.

Figure 7. Vertical fracture, trending 125° (N65°W - S65°E) laterally displaced along a clay seam at the location of 12.19.1983 gas blowout in area 160 of the Kerr-McGee mine (See Fig. 2 for location).

B. A continuous mining machine with a protective metal grating to protect the operator from debris resulting from a potential gas blowout. (Kerr-McGee mine).

#### Eddy Mine (National Potash Company) - 1973, 74

The Eddy mine is located about 17 miles northwest of the WIPP site (Fig. 2). Three incidents of roof and floor fall in this mine accompanied by sudden release of gas were reported in 1973 and 1974 (Table 1). Four reports by the State Inspector of Mines dated 12/20/73, 2/25/74, 4/18/74 and 11/27/74 described these incidents in detail (App. C). There were floor breaks and roof falls on 12/16/73, 2/24/74 and 11/27/74 due to release of pressurized gses in this mine. There were several injuries as a result of the 11/27/74 incident.

#### Gas Blowouts Prior to 1973

1 .

Written records of older incidents of gas blowouts in the Carlsbad area potash mines are difficult to trace, but several people associated with potash mining in the area remember such incidents. For example, Sidney R. Kirk (MSHA) recalls (verbal communication) an incident of sudden roof-fall, most likely associated with a gas blowout at the U. S. Borax mine (now known as Mississippi Chemical). This incident in which one miner was killed occurred around 1960.

The U. S. Bureau of Mines conducted a detailed investigation into the occurrence of gas in the Carlsbad Potash District mines in 1963-64. The report of their investigation (Rutledge, et al, 1964) is included as Appendix D of this report. A total of 169 vertical holes, 20 to 40 feet deep were drilled into the roof at six mines. Gas under pressure was found in 67 of these boreholes. A total of 91 "blows" were encountered, 87 of which came from the clay seams. Seventeen holes were examined with a stratascope and the examination revealed that the gas emitted from the clay seams was contained in small yugs about 0.1 inch in diameter, connected by hairline cracks. Gas pressure in clay seams was found only in holes drilled in intersections of drifts. Gas between intersections was found in only 1 hole where it occurred in a small pocket in salt. As the pressure of gas in boreholes was released the roof rose visibly. As a result of this investigation, the authors recommended that "stress on the immediate roof strata due to gas pressure may be relieved by drilling 10 to 20 foot deep vertical holes in each intersection as soon as practicable after first mining while ventilation is still intact." This practice has been adopted by several of the mines in the area.

### Occurrence of Gas at WIPP Site

I

• • • •

Gases have been encountered during the drilling of exploratory holes for WIPP at several stratigraphic horizons in the Salado formation. Table 2 summarizes the available information and was prepared from data provided in Griswold (1977) and the Basic Data Reports for the boreholes. Figure 10 shows the locations of these boreholes. It clearly demonstrates that gases occur in the upper, middle and lower sections of the Salado Formation.

More than 10,000 feet of excavation at the WIPP repository horizon has been completed to date. Although no written record of gas encounters, even minor "poofs", is available for the WIPP excavations, several project participants informally discussed with the author instances of release of minor amounts of gas accompanied by hissing sound during the excavations for WIPP. The occurrence of gas 10 to 15 feet above (in Anhydrite "a" and "b" layers) and 10 feet below the WIPP repository (in Marker Bed 139) has been studied in detail (U.S. DOE, 1983). The maximum rate of flow of gas was encountered 850 ft south of the 12 ft exploratory shaft. Hole S850A was drilled vertically upwards from the roof of the East 140 drift and encountered as much as 12,280 cc/minute flow rate of gas emanating from Anhydrite "b" layer. A hole (\$850C) drilled vertically down at the same location, to a depth of 14.8 feet, intercepted gas in the clay layer below Marker Bed 139. The initial flow rate was approximately 1200 cc/minute. One day after completion of hole 850-C, the hole was found to contain approximately 2 liters of brine. Gas was encountered in 9 boreholes drilled from the roof and floor of WIPP drifts. Pressure buildup in these holes ranged from 10 to 120.6 psi. A typical flow hydrograph of the WIPP gas testing borehole shows a periodicity of flow. Each hole has a different magnitude and periodicity of flow. Although a possible explanation is that the flow may be influenced by changes in ambient pressure in the mine, it has not been demonstrated and there might be other explanations for the pulsating character of gas emanations.

#### CHEMICAL COMPOSITION OF SALADO GASES

Table 3 shows a summary of the chemical analyses performed on Salado gases from near the WIPP repository horizon and from the McNutt Potash Zone. The analyses show that nitrogen is the primary constituent with concentrations recorded from 76.3% to 96.5%, oxygen accounts for 0.2% to as much as 22% and methane constitutes from 1.07% to a maximum of 7.8%. Very small amounts of  $CO_2$  and  $C_2H_6$  are also present. It should be kept in mind that the process of gas sampling is somewhat tricky and that it is quite likely that the samples showing oxygen content much above the average values may have been contaminated by air. The highest concentration of methane (7.8%) was found in the gas sample collected from the clay layer below Marker Bed 139 in the borehole 850-C drilled 15 feet into the floor of the East 400 drift, 850 feet south of the 12 foot exploratory shaft at WIPP.

There has been some confusion about the nature of gas outbursts in the Carlshad area potash mines. Use of the word "explosion" to characterize the sudden release of pressure and consequent flying of rocks and debris has been misunderstood. It is therefore appropriate and pertinent here to examine the "explosibility" of Salado gases.

Webster's dictionary defines "explosion" as, "the act or an instance of exploding as a large scale, rapid and spectacular expansion, outbreak, or upheaval." Similarly, one of the meanings of the word "explode" is, "to burst violently as a result of pressure from within." The violent outbursts caused by the sudden expansion of gas due to release of pressure from the trapped gas in the rock strata can thus be best characterized as "explosion." However, the word also connotes explosibility in a chemical sense. The Salado gases do not appear to be "chemically explosive." For this reason the terms "outburst" or "blowout" have been used in this report.

Coward and Jones (1952) have discussed the potential for explosion of mixtures of methane, air and nitrogen. Figure 11 shows this relationship graphically. It shows that a minimum of 5% methane and 12% oxygen is required for a mixture to be explosive. Table 3 shows that the Salado gas typically contains about 2% methane and 7 to 11% oxygen. Such a mixture is not chemically explosive. The

Figure 11. Relationship between the composition and the explosibility of mixtures of methane, oxygen and nitrogen (From Coward and Jones, 1952).

qas sample obtained from Marker Red 139 at WIPP contains the highest percentage of methane (7.8%) but too little oxygen (1.4%) to make it explosive in a chemical sense. One sample from the Eddy Mine of National Potash Company was analyzed to contain 12% oxygen and 16% methane (App. C), but its accuracy is questionable.

#### THE ORIGIN OF GAS

L

All salt deposits contain some fluids (brine and gas) and the Salado formation is no exception. Within halite crystals, gas can often be seen as a bubble within a fluid inclusion. To estimate the percentage of fluids in the halite crystals of the Salado Formation, 35 selected core samples from ERDA-9 borehole were heated to 500°C and weighed before and after the expulsion of gas and brine. The results showed that more than half the specimens showed only 0.5% weight-loss. The maximum wight-loss recorded by one sample was 3.5% (Powers, et al, 1978). Since most of the fluid in the inclusions consists of brine, total amount of gas trapped within the salt crystals is negligible.

Almost every reported encounter of gas in the potash mines as well as near the WIPP repository is associated with either clay seams or clay-enriched zone of salt. The composition of the gas shows that it was most likely derived from the original atmospheric air at the time of deposition of Salado. The gas is depleted in oxygen most likely due to the high chemical activity of oxygen which allows it to react with a variety of elements to form oxides. Methane must have originated from decomposition of marine organic life during times when clays were deposited in the Salado sea. The presence of gas near the clay layers is probably due to the contrast in the mechanical properties of clay and salt. Gas originally trapped must have migrated along crystal boundaries until it reached the impermeable clay layer.

An important observation made in the Kerr-McGee mine is that the violent gas outbursts have left a near vertical fracture which can be seen in the roof and to 1-2 foot below the roof along the walls of the drift. Does a fracture represent a cavity in which the gas was trapped until released or was it created due to the sudden release of gas generally disseminated in "vugs and hairline cracks" as observed by Rutledge et al (1964) through a stratascope? If gas is contained in a discrete fracture until the pressure is released, it must be in equilibrium with the lithostatic pressure at that level. This could have happened by the trapped gas coalescing in a fracture, keeping it open as the gas became pressurized due to salt creep, until the gas pressure in the fracture reached the magnitude of lithostatic stress. This would mean that gas -pockets in deeper strata would be more pressurized. Alternately, gas could

remain trapped in permeable zone at the contact of salt and clay, without being pressurized to lithostatic levels. Release of pressure in such a case would be less violent and would not necessarily be higher at greater depth.

There appears to be a preferred direction of orientation of fractures associated with gas blowouts. The fractures are mostly oriented in a WNW-ESE direction. It is possible that the fractures were created by some geological activity in the past and gas from the surrounding region migrated into them and later became pressurized due to salt creep. The stress field which would induce WNW tensile fractures should have been perpendicular to that direction, i.e. NNE. There is a lamprophyre dike with an approximately NE trend which is exposed in the northwestern part of the Kerr-McGee mine. It is likely that these fractures were created when the dike intruded into the Salado salt about 37 million years ago. The fractures associated with gas blowouts are, however, not continuous for more than a few tens of feet--they are not intercepted in parallel drifts. This indicates that the fractures were either formed "en echelon" or that they result from the localized explosive activity associated with sudden release of pressure every time a blowout occurs. A clear answer to this question will require extensive experimental work in the areas where gas blowouts have been observed.

25

.

#### CONCLUSIONS AND RECOMMENDATIONS

#### Conclusions

t

**۱** 

]

Based upon the facts and discussions presented in this report, the following conclusions can be drawn concerning the occurrence of gas in the Salado Formation.

- 1. Gas can be found at almost any level within the Salado Formation, generally near clay seams associated with the marker beds.
- 2. The gas consists primarily of nitrogen with some oxygen and methane and lesser amounts of carbon-dioxide and ethane. The composition of the gas does not make it "chemically explosive."
- 3. Smaller amounts of gas in isolated pockets at low pressures is very common. Such pockets may consist of porous zones at the boundary of salt and clay where gas may be trapped in "vugs connected by hairline cracks." The pressure in such zones may be less than lithostatic. Encounter of such zones of small amounts of gas at low pressures (knows as "poofs") is almost a daily occurrence in the Carlsbad area potash mines.
- 4. Occassionally gas has been encountered under high pressure. Sudden expansion of gas due to release of high pressure creates an explosion or "outburst" which has occasionally resulted in death and/or injury to miners. At least seven such outbursts have been documented. Outbursts not involving a fatality or serious injury usually go unreported. No such incidents were reported to the state and federal authorities between April, 1976 and December 1983. After the fatal accident involving gas release on Dec. 13, 1983 at Kerr-McGee mine, two more incidents of gas outbursts at the same mine came to light within a month. Out of these, the one on Dec. 19, 1983 was not reported to the State Mines Inspector. It is thus a safe assumption that violent outbursts of gas are more common in the potash mines than generally assumed.

- 5. Each violent outburst exposes an open vertical fracture. Due to the similar alignment of these fractures in a WNW direction, it is thought that the gas is trapped in fractures which may have been opened due to a geological factor such as the emplacement of a dike. If this is true, the gas pressure within these vertical fractures would have to be in equilibrium with the horizontal component of the litholostatic stress, or approximately at 1500 psi pressure. Sudden release of such a high pressure would dislodge and move large chunks of rock and machinery if caught in the outburst.
- 6. Small amounts of gas, often emanating in a cyclic period, have been encountered in zones a few feet above the ceiling and below the floor of WIPP excavations. Chemical composition of this gas is similar to the gas found in potash mines, 600 feet stratigraphically above the WIPP repository.
- 7. No encounter of gas, not even small "poofs" have been officially reported from more than 10,000 feet of excavations for WIPP. However, there are hearsay accounts of such encounters.
- 8. There is a low probability of finding pockets of highly pressurized gas at WIPP since none have been encountered after 2 miles of drifts have been excavated. However, the possibility cannot and should not be ignored. If the hypothesis of gas filled fractures being at a pressure equivalent to the horizontal component of lithostatic stress is correct, such fractures if encountered at WIPP, would result in a larger pressure drop than the ones at potash mines level.

#### Recommendations

The following recommendations are made for future operations at the WIPP site.

- Collect and publish the information on even minor encounters of gas "poofs" during the WIPP excavations - their location, description, associated fractures and any unusual geologic features in the vicinity. A form being used by Kerr-McGee mine for this purpose is attached as App. E.
- 2. Map any fractures and areas of excessive moisture seeps in the excavations.

27

3. Continue the practice of drilling advance exploratory holes before cutting a face with the continuous mining machines. These holes should be drilled slanted upwards to intersect the clay layer near the ceiling.

ţ

- 4. Install protective metal grating on the continuous mining machines similar or better than the ones installed at the Kerr-McGee mine.
- 5. Check the mining machines for any loose parts which may get removed and fly about in the event of an explosion. Remove or re-install such parts to prevent this possibility.
- 6. Establish procedures to not allow any unnecessary personnel near an operating mining machine.

INVESTIGATION INTO THE OCCURRENCE OF GAS PRESSURE ABOVE THE FIRST AND TENTH ORE ZONES IN THE POTAGE DISTRICT, CARLSBAD, NEW MERCICO

December 3, 1963 through March 5, 1964

#### DITRODUCTION

This report summarizes the investigation of the occurrence of gas pressure above the ore cones at six mines in the potash district, Carlobad, New Mexico. Individual reports have been submitted for each mine investigated.

Four of the mines were mining sylvite from the first ore zone, one was mining sylvite from the tenth ore zone (located about 200 feet above the first ore zone<sup>1</sup>), and one was mining sylvite from the first ore zone and langbening te from the fourth ore zone. Tests at this last mine were confined to the first ore zone. Cover ranged from about 883 feet to 1698 feet. Four mines were being worked by a room-and-pillar system, and two mines by a retreating punel system.

Test areas were selected for their physical characteristics, and the probability of finding gas pressure. Areas investigated ranged from newly mined sections to sections that had been open up to 26 years. Pillars had not been extracted in any of the test areas; however, at three mines the test areas were adjacent to sections where pillars had been extracted. At one mine pillars showed evidence of weight, and three old roof fulls were observed.

At all the mines investigated, programs of drilling holes to relieve gas pressure were in operation. Methods varied from drilling 40-foot verticle holes in every intersection to drilling occasional inclined holes which released any pressure within a few feet of the back. At several mines, holes for rock bolts, in and between intersections, relieved any pressure within 6 feet of the back.

#### EQUIPHENT

Holes were drilled in the back with roof bolting machines, using sectionalized auger steel and tungsten carbide-tipped fishtail bits. Three-inch diameter holes for the stratascope were drilled with special one-pass bits, or small holes were enlarged with a locally designed reamer.

Rock struta was observed with a stratascope on loan from the Bureau of Mines Roof Control Research Group. The strutuscope consisted of a sectionalized periscope equipped with a light in the head of the instrument for illumination.

1. C. L. Junes, C. G. Bowles, and A. R. Disprow, Generalized Columnar Section and Rudioustivity Log, Carlsted, Potuch District, 1954. Four sections of 5-foot tube allowed observations to be mode as far as 20 feet int, the hole; however, as the optics in this instrument did not provide progressive mignification of the image as additional sections of tube were added, a very small image was obtained at 15 to 20 feet. The stratascope was equipped with a camera.

Gas samples were obtained with an aspirator bulb and tubing and collected in vucuum bottles. A packer and pressure gage assembly was used to measure gas pressure. A dial gage, capuble of detecting movement of 0.001 inch, was used to determine roof movement when gas pressure was released. Velocity of gas escaping from drill holes was measured with a velometer capable of reading to 9,000 feet per minute.

#### PROCEDURE AND DATA

At the six mines investigated, a total of 169 vertical holes were drilled from 20 to 40 feet into the roof; 115 of the 169 holes were drilled in intersections. Gas under pressure was found in 67 (58 percent) of the intersections drilled. A total of 91 "blows" were encountered; 15 were in intersections containing gas at 2 elevations above the back; and 4 were in intersections containing gas at 3 elevations above the back. Forty-eight holes were in intersections containing gas at 1 elevation. Gas pressure was released in only 1 of the 42 holes drilled between intersections. This "blow" was classed as light and the gas appeared to have been released from a salt layer." In order to determine if one hole relieved all the gas pressure in an intersection, 12 additional holes were drilled in 10 intersections. None of these additional holes released gas pressure.

Thirty-three holes were examined with the stratascope in order to determine the characteristics of the roof and the location of gas-bearing strata. At one mine the roof strata was examined without instruments in two raises driven to a height of about 11 feet above the back. Locations of mud and polyhalite seens in the roof, as determined by observation of drill cuttings, agreed closely with locations determined by the other methods. In all mines except one, the 20 feet of strata above the back contained two or three mud sears and a polyhelite seam. The polyhalite seam was not observed in mine "7"2. Most mud seems were made up of interbeded salt and mud, and the polyhelite seam vas composed of interbeded salt and polyhalite. Thin mud bands were generally present at the top and bottom contacts of the polyhalite layer and salt members. The mud and polyhulite seams were found to be continuous over each area investigated, and were probably continuous over considerably larger areas. At one mine, openings up to two inches in thickness were found in the first and second mud seams. This area had been opened approximately 20 years prior to this investigation, and gas pressure was not found in these mud seems.

- A "blow" is classed as light when the release of pressure from a hole can be detected. A medium"blow"vill clean the settled dust from the rotary head of the drilling machine. A heavy blow vill clean the settled dust from the floor of an intersection.
- 2. See appendix 2 (list of mud seems) 63

Eighty-seven of the 91 "blows" encountered came from the mud seams, or mud bands at the contacts of the polyhalite band and salt. Seventeen holes, "Which produced 19 of the 57 "blows", were examined with the stratescope. [

Which produced 19 of the 57 "Ulows", were examined with the stratescope. The examination of the holes revealed that the gas emitted from the nud seems or mud bands which contained small vuggs, "about 0.1 inch in diameter, connected by hairline cracks.<sup>1</sup> This pattern was found in every examined hole that "blew". Three holes produced light "blows" from salt members, and stratescope eximination of one of these three holes revealed that gas emitted from a small vugg, 0.1 inch in diameter, in a zone of what appeared to be coarse salt crystals.<sup>2</sup> (me hole produced a light "blow" from small pin holes in a bolyhalite band.

A series of 4 holes were drilled in 1 intersection to determine the lateral extent of vuggs and hairline cracks. The first hole relieved gas pressure at the contact between polyhalite and calt. Examination of this hole showed that the gas was released from 0.1-inch diameter vuggs connected by hairline cracks. The second hole drilled 18 inches from the original hole did not release gas; however, vuggt and hairline cracks were visible at the same elevation as in the original hole. The third hole was drilled near the pillar line, 15 feet 6 inches from the original hole. Cas was not released but vuggs and cracks were visible. The fourth hole was drilled 35 feet from the original hole, and 8 feet outside of the intersection; no gas pressure was detected, and no vuggs and cracks were visible in this hole.

In order to determine whether gas was present in areas other than intersections a series of 5 holes on 20-foot centers were drilled into the roof between 2 intersections that had produced "blows". None of the 5 holes released gas. Since the possibility existed that holes drilled in intersections could have relieved any gas pressure in the area between intersections, a series of holes were drilled in rooms and breakthroughs before drilling the intersections None of the holes in the rooms and breakthroughs relieved gus pressure; however 6 holes in 6 of the intersections produced "blows".

Gas pressure in one hole in the center of an intersection was sealed in, by means of the packer and gage, and pressure built up to 50 psi. A second hole drilled 20 feet from the original hole, and 6 feet outside of the intersection, did not reduce the pressure in the original hole. Another hole drilled in the intersection, 7 feet from the original hole, relieved the pressure in the original hole.

From the data collected during this investigation, no explanation can be offered as to why only contain intersections contained gis. Mud seams must have a certain degree of permeablity to permit gas to collect in idtersections

See appendix 1.

7

1. . . **.** . . .

.....

however, the permeatility must be very low, or significantly reduced by produce due to mining as Attempts to relieve gas pressure from interpections by drilling in rioms and breakthroughs did not produce any noticeable results.

The back could be heard "working" when gas pressure was released through drill holes. Measurements with a dial gage indicated that the back moved upward when gas pressure was released.<sup>1</sup> Roof movement ranged between 0.001 and 0.030 inches when "blows" were encountered from 2 feet to 17 feet above the back. The maximum movement of 0.030 inches was observed when 3 "blows", at elevations above the back of 5 feet 9 inches, 9 feet, and 10 feet 6 inches, were relieved with a single drill hole. The upward movement of the roof took place rapidly, and the total rise apparently depended on the volume of gas relieved and height above the back of the gas-bearing strata.

Direct readings of gas pressure were difficult to obtain due to the short duration of the "blows" and the time required to remove drill steel from a hole; however, three pressure readings were obtained in 3 separate holes.<sup>2</sup> These measurements were taken where gas was emitted from the mud band at the top of a polyhalite layer, and from the second mud seam. All 3 "blows" were classed as light; however, a pressure of 60 psi was recorded at one hole. Pressure built up rupidly after the packer was installed, reached a maximum within 20 minutes, then dropped off very slowly, probably due to leakage around the packer and/or leakage into the lower mud seams. It is believed that the pressures measured were only a fraction of the original pressures in the intersections, due to the volume of gas lost while removing the drill steel and setting the packer.

Fourteen vacuum-bottle samples were taken by aspirating gas out of plugged boles which were still "blowing" at the time of sampling.3 Thirteen of the analyses indicated that the gas was not explosive. Sample W-1568 contained 9.24 percent effective combustible material and would become explosive, over a limited range, when mixed with air.<sup>5</sup> The gas represented by this sample did not create a hazard due to the short duration of the "blow" and the rapid dilution in the ventilating current.

Velometer readings could not be used to calculate initial pressures due to the high velocities of the escaping gus, the presence of the drill steel in the holes, and the time necessary to "blow" out the cuttings. "Blows' classed as approaching medium had velocities in excess of 9,000 feet per minute.

#### SUMARY

1. Cas under pressure was found primarily in 3 mud seems, and in mud bands at the top and bottom contacts of polyhalite layers.

2. Gas pressure in mud seems or bunds was confined to intersections. Gas between intersections was found in only 1 hule where it occurred in a small pocket in the salt.

3. Mud and polyhelite seams were continuous over each area investigated.

4. Where gas occurred in mud seems or bands in intersections, it emitted from small vuggs 0.1 inches in diameter connected by hairline cracks. The vuggs and cracks were observed to be distributed through out the area of the intersections, and one hole was sufficient to relieve all pressure to the depth drilled.

5. All "blows" encountered were classed as light or medium, and were of short duration. The volume of gas released appears to be consistent with that volume which could be expected to be confined in the vuggs and cracks in the area of an intersection. Large pockets of gas were not found during this investigation.

6. Analyses of vacuum-bottle samples showed that gas exitting from roof stratu, with one exception, was nonexplosive. One sample indicated that gas emitting from the third mud seem at 1 mine would become explosive, over a very limited range, as the gas was diluted with air; however, the gas represented by this sample did not create a hazard due to the short duration of the "blow" and the rupid dilution in the ventilating current.

7. Direct readings of gas pressure indicated that initial pressure in aud seems can be greater than 60 psi.

8. In the intersections that were measured, the back rose from 0.001 to 0.030 inches when gas pressure was released.

9. "Elcvs" clussed as approaching medium had velocities in excess of 9,000 feet per minute.

10. Gas pressure in the roof strate has a definite effect on the roof, as evidenced by measurements of gas pressure and the rise of the back as pressure was relieved.

.11. During this investigation, the relief of gas pressure through small diameter drill holes did not present an explosion hazard.

12. Determination of initial formation pressures, and the pressures necessary to cause fillure of the roof were beyond the scope of this investigation; however, this inf rmation could be of considerable value to the parties involved.

# CONCLUSION

The information obtained during this investigation indicates that stress on the immediate roof strata due to gus pressure may be relieved by drilling 10 to 20-foot deep vertical holes in each intersection, at soon as practicable, after first mining while ventilation is still intact.

Means should be provided to sample the atmosphere in the vibinity of the drill holes for total combustible content in the event of an unusually long or violent "blow".

#### ACKNOWLEDGHENT

The cooperation of the munugement and employees of the International Mineruls and Chemical Corporation, the National Potash Company, the Duvul Corporation, the Potash Company of America, and the United States Borax and Chemicul Corporation, is gratefully acknowledged.

The United States Potash Company was the original discoverer and first producer of underground mined potash are in North America and commenced active production of potash in 1931. In July 1950, the company merged with United States Borax & Chemical Corporation and is now a Division of that exportion.

The mine is located twenty-two miles east of the city of Carlsbad and the refinery is located sixteen miles couth of the mine. The mine was placed where the cre was found and the refinery placed where there was sufficient water for a dissolving and re-crystallization plant.

For twenty-three of the last twenty-six years, the potash one was mined with the room and pillar method, taking approximately sixty percent extraction and leaving forty percent in pillars. These fillars are generally fifty-eight feet by fifty-eight feet square. Three years ago, it was decided that removal of as large an extraction as possible from these pillars should be contended.

The first visible evidence of subsidence on the surface is by small hairline cracks which repidly develop into openings measuring up to approximately one inconvide and one hundred fest long. As the face retreats underground, these tension eracks disappear. About the boundaries of the final mined area which have been unwarked for any length of time, these cracks appear ind become larger. With continual strain and erosional effects, some of the cracks develop into mised able openings measuring six inches to two feet wide and with an unknown depth. With continued provion, the walls of the cracks fall into the bottom, thus widening and filling the openings.

In the prevent stage after two years, some of the openings appear as slump holes measuring some six to eight feet across, ten to thirty feet long, and five to fifteen feet deep. The geologic structure inrough which these forces are transmitted is mother typical of build will supposits in the area. The buff dolomite section at approximately four hundred feet below the surface is a water none of considerable magnitude over quite an extensive area. The fact that both the salt and potash are highly soluble makes it imparative that the section between this buff dolomite and the underground salt and potash beds below must not be ruptured. The potash bed, which varies from five to fifteen feet in height and lies more or less horizonual, is approximately one thousand feet below the surface and is normally overlain by a salt section some five hundred feet thick. The shale and clay strata below the water zone and above the salt section form the impervious layer which protects the salt section from the water above.

The effects of subsidence over the surface area are much larger than the actual final mined area underground. In those places where final mining has been carried to the limits of the orebody, subsidence effects have been observed some seven hundred feet beyond the limits on the surface. In those places where final mining stopped in a first mined area, subsidence has been noted for distances as great as one thousand two hundred feet beyond the limits of final mining. Principally for this reason, a large zone about the hoisting shafts has been prohibited to final mining activities until all other mining is completed.

In present operations, there are two types of mining in use. The first is known as conventional mining which utilizes undercutters, drills and blasting, after which the one is moved from the face with loaders and shuttle cars. The other method is with continuous mining machines using extensible and mainline haulage belts. In both of these operations, final mining is being carried on. The conventional final mining system is used generally in high one in which it would be uneconomical to use a continuous mining machine.

In cases where a mud seam or zone of weakness occurs in a pillar, it will, of course, crush and fail at this point. Frequently when the mud seam is just above the back or just under the floor, the pillar will punch through into the weak zone. Additional effects caused by the mud seam just above or just below an entry are frequent sags and falls of roof slabs and neaving of the floor.

Even in the event that roof slabs begin to fail over haulage ways, an attempt is made to control their subsidence until the haulage way is abandoned. In controlling roof slabs, cribbing stulls and roof bolts are often used. These measures usually suffice to keep the haulage ways open but occusionally it is necessary to blast down a slab and remove it.

It is thought that roof slabbing and floor heaving are caused by the vertical pressure and certain resulting forces. The vertical pressure through a punching action causes the tendency for the floor to rise in the entry and the back to sog. The other resulting forces the thought to be the movement of clay in the clay scale from above and below the gillars out into the floor and back in the entires. It is also throught that Bend pressure exerted on the floor androof slabs from the expanding pillars helps to cause the initial separation of the slabs.

The second type of mining in our operations is in the continuous miner sections. About five years ago we commenced the use of continuous miners, and in this operation a different type pillar was receivery due to the limitations of the machine. The general mining pattern with this motiod leaves pillars one hundred feet long and thirty-five feet wide after first of ing. In final mining, these pillars are reduced to such size that from mining-five to minity-eight percent extraction is being obtained. The back stands well immediately after minity but with such a large percentage of extraction, subsidence is relatively rapid.

In graphically plotting subsidence, the major amount of movement underground is estimated to be approximately twelve fact, while the major subsidence on the surface is approximately eight and one-half feet. This would appear to indicate that very little breaking is to i < plain the strata above the mined-out area and that the overlying beds are more or less strong uniformly.

In plotting the movement of one particular station on the surface and underground in . . final mined area, it was found that for approximately thirty days subsidence was extremely regile The total height of the mined-out area was originally 12.75 feet. For the first thirty days after final mining, there was apparently little novement; but between thirty and sixey days, the underground workings at this point had subsided 3.25 feet, while the point above on the surface hid dropped 0.75 flet. At the end of one hundred days, the back had come down a total of six feet, while subsidence on the surface measured 2.20 feet. After one hundred and forty days, the station underground had one-half feet. Due to the bad conditions of the back underground at this time, observations were discontinued. On the surface, however, the point continued downward, measuring six feet total drop after two hundred days. It was at approximate this point that the sharp rate of subsidence enangedabruptly. At the end of one thousand days, the surface station had subsided a total of 7.50 feet, an increase of 1.50 feet in the last eigh hundred days.

In graphing the movement of this station, it was found that the line was not continuously downword but indicated that subsidence, both underground and on the surface, came in waves or intervals, and in some cases the ground actually rose from the previous month's reading. From our closest observation in a single instance, it appeared that surface subsidence became measurable approximately thirty-five days after subsidence was noted underground.

In the first study of subsidence movement, a grid was set over the area to be mined with stations on five-nundred foot spacing, both east-west and north-south. These stations were triangulated in each month and a record of their movement was noted. From this date an approximate limiting angle of 51 degrees - 30 degrees has been calculated, the limiting angle, of courd being measured from a line truen vertically up from the edge of advance and a second line drawn upward from the edge of advance to the cuternost point where subsidence was observed on the surface. This limiting angle is important in determining where surface structures will be affected by subsidence. There are many factors which contribute to the degree of the angle. Those principally responsible are:

(1) The overlying strata through which subsidence takes place, this angle being relatively small for strong rocks and rolatively large for weaker members, the total limiting angle, of course, being the sum of the various limiting angles up through the differentstrata.

(2) It has been observed that the limiting angle is greater in areas where final mining operations are bordered by first mining operations. Strictly speaking, this is not a true limiting angle because extraction outside the area effects an increase of the angle. However, from the practical point of view, it is quite necessary to take this influence under consideration. We have observed in some cases a limiting angle as large as 51 to 30 degrees. It may be when the ground completely stabilized that this argle will become comewhat gronton.

The limiting angle, of course, can only be manused well after final mining has seen completed and the ground has more of less become suchlided. Up until this point there is a definite lag of subsidence behind final mining operations.

Recently a line of stations on one-hundred foot centers was placed over the center of an area which was to be final mixed. In addition to giving much eloser control on succisence data, we can determine the amount of strain (elongation and compression) between there points. This method of computing will give a more accurate limiting angle and an angle of repose which is the complement of the limiting angle, and the angle of break. The angle of break is of considerable interest as it is the line through which the greatest force of shear is emerged. This argle is measured from the horizontal to a line which is drawn from the edge of nivance of the retreating face underground up to a point of maximum tension strain, as plotted from the field data.

It is exploted that with continued study, more detailed information on the characteristics of ground movement, as applied to salt-bedded deposits in the Carlobad district, will below available.

 $\mathcal{D}$ 

Mr. President, critics of S. 717 have claimed that the imposition of civil penalties is a punitive measure, that it is an attempt to punish operators who do not comply with the act's requirements. Well, in my mind this is merely a question of attitude. I prefer to think of the civil penalty as a means of encouraging compliance, not as a means of punishing disobedience.

We have seen, in recent years, a much greater improvement in the rates of fatalities and serious injuries in the mining of coal, than we have seen in noncoal mining. I believe that the civil penalty system under the Coal Act is a major factor contributing to this improvement in what we are really getting at—the safety and health of our Nation's miners.

S. 717 provides a streamlined procedure for the collection of these penalties while insuring fairness to the parties. The bill provides a procedure which enables the questions arising out of civil penalties to be litigated quickly and with finality.

Under this procedure, an independent administrative tribunal assesses the penalties, and review of penalty assessments is based on a substantial evidence test, the prevalent test for court review of administrative determinations under our system.

We know, however, that there is a hard core group of operators for whom civil penalties provide little encouragement to comply with the requirements of the law. These operators apparently find it easier, and perhaps cheaper, to simply pay penalties rather than do what they must to get their mines in shape and provide true and lasting protection for their workers.

That was the situation the committee's investigators found at Scotia—a pattern of habitual violations of the act's requirements which would be cited by the inspector and abated by the operator. But the operator would then permit the mine to lapse back into violation, exposing miners to these risks all over again. This was repeated.

At Scotia there were 62 ventilation violations in the 2 years prior to the explosion. It is likely that it was just this improper ventilation which was instrumental in an explosion of accumulated methane gas.

This bill provides two new enforcement procedures addressed to these situations. One is a new closure order sequence, which is triggered by the finding that a pattern of violations exists in a mine which could substantially and significantly affect the health and safety of miners.

This new mechanism permits the Secretary to issue an order closing all or the affected portion of a mine every time another such violation is found, until an inspection of the entire mine indicates that there are no more violations of the 'ype which established the pattern.

The other new sanction available in such situations permits the Secretary to ask a Federal district court to fashion appropriate relief in cases of chronic and habitual violations of the act by operators.

Mr. President, I think these new enforcement tools are true responses to the

inadequacies of enforcement in our present law which the Scotia tragedy so clearly demonstrated.

 $\Sigma$ S. 717 addresses the inadequate enforcement of our mine safety laws in another way. It transfers responsibility for the enforcement of this program to the Department of Labor.

In the committee's judgment, the responsibility for insuring workers' health and safety logically belongs with the Department which has as its overall duty the responsibility of safeguarding workers' rights. Yet the committee recognizes that miner health and safety calls for particular expertise and a special expenditure of effort. It is for that reason that S. 717 insures that the mining enforcement agency will maintain its independence within the Labor Department.

Further, in order to insure that the mine safety and health program will not be denied the technical mining expertise of the Bureau of Mines, the safety research and training functions which are integrally related to this technical expertise are retained in the Interior Department. Under this arrangement, the Secretary of Labor will be able to determine his safety research and training needs, and arrange to have the appropriate research and training done by the Interior Department. The considerable skill and experience of the Bureau of Mines will thus continue to be directed toward furthering the health and safety of our Nation's miners.

Mr. President, there will be charges that this attempt to improve the health and safety of our Nation's miners will be costly to the mining industry and that the cost to the consumer of energy and mineral products will increase. Possibly that is the case.

Mr. President, we must consider the cost we now pay in human suffering. One death and sixty-six disabling injuries every working day is a cost which no civilized society should permit itself to pay for extracting minerals.

Our country is now turning to address our natural energy shortage. The President has already sent to us a comprehensive plan to increase the development and exploitation of our energy and mineral reserves. I believe that an effective mine safety and health program must be put in place first—and must be the firm foundation upon which we will build our national energy program. Otherwise, we will continue to pay for our energy and minerals with the dreadful currency of human lives and limbs.

Our national energy needs should not be met at the expense of our Nation's miners and their families. With the possibility of greatly increased mineral extraction on the near horizon, the time has come for reform of our inadequate mine safety and health program. Our miners should have to wait no longer. Our Nation should want to wait no longer.

Mr. President, this bill has the support of the President and his administration.

The Secretary of the Interior and the Assistant Secretary of Labor have told the Labor Subcommittee that President Carter considers the changes to our

mine safety and health program made by S. 717 to be essential, and of a high priority.

Mr. President, the Committee on Human Resources has felt this urgency for a long time.

S. 717 has been carefully drafted and considered by the committee, and I am glad that it is on schedule now for the Senate to make its determination.

Mr. President, I am happy to see that the ranking member of our committee, the Senator from New York (Mr. JAVITS), who has been one of the leading architects of all of our safety laws, is now ready to advance another necessary cause, S. 717, before the Senate now.

Mr. JAVITS. Mr. President, we have before us today a bill, S. 717—the Federal Mine Safety and Health Amendments of 1977, which was unanimously reported to the Senate last month by the Human Resources Committee. I am pleased once again to join the chairman of the committee, Mr. WILLIAMS, in urging the adoption of a measure to bring about a marked advance in the safety and health of our Nation's working men and women.

This bill is intended to strike a new balance in the longstanding antagonistic goals of maximizing production of energy and mineral resources on the one hand, and, on the other hand, affording the maximum safety and health protection for the workers who extract those resources in what all recognize is inherently a highly hazardous occupation.

With greatly increased emphasis on coal production to meet our future energy needs, we must be sure that accelerated production is accompanied by an improvement in the rate of fatalities and disabling injuries among miners. To this end, the bill makes a number of improvements in the standard setting and enforcement provisions of the Federal Coal Mine Health and Safety Act of 1969.

S. 717 will at last also bring about a balance in worker protection between coal miners and other miners who have been inadequately protected under the far less comprehensive and stringent provisions of thee Federal Metal and Non-Metallic Mine Safety Act of 1966. With the enactment of this bill, all miners, whether coal or noncoal, whether underground or surface, will be afforded equal protection against the hazards of their common occupation. To trais end, the bill repeals the Metal Act and vests all authority in the Secretary of Labor under one new statute, which nevertheless leaves intact the appropriate differences in standards between the coal and noncoal operators in the mining industry.

This bill is a product of extensive oversight activities on the part of the Human Resources Committee that have continued over the past 7 years. The committee has investigated several of the terrible disasters that have taken the lives of miners during this period. The Human Resources Committee has also received a series of critical reports from the General Accounting Office on the state of the present mine health and safety program.

After all of this careful examination,

Bulletin 503 Bureau of Mines

# LIMITS OF FLAMMABILITY OF GASES AND VAPORS

BY H. F. COWARD AND G. W. JONES

UNITED STATES GOVERNMENT PRINTING OFFICE, WASHINGTON : 1952

# METHANE

# METHANE IN AIR

When a spark was passed near the lower confines of methane-air mixtures standing over water in a vessel 6 feet high and 12 inches square in section, the following observations were made (63):

5.1 percent methane.—A vortex ring of flame inveled upward about 12 inches, broke, and died out as a tongue of flame about 12 inches higher.

5.3 percent methane.—In one experiment the ring of flame resolved itself into a flame that traveled steadily to the top of the vessel; in other experiments the flame became extinguished during a violent uprush on one side.

5.6 percent methane.—A steady flame with a convex front passed throughout the mixture.

These experiments have been repeated with a glass cylinder 7 feet in height and 10 inches in diameter. The limit observed was 5.32 percent methane. Steady conditions were obtained more easily in the 10-inch tube than in the box (68).

Independent observers conducted experiments in a vessel similar to that first described, which led them to conclude that the lower limit for inflammation upward was about 4.9 percent methane (45). Comparison of the two sets of experiments shows, however, that they were conducted differently. In each set the gas was ignited electrically at the lower end of the vessel; in the first set the flame traveled toward the closed end with a release behind the flame, but in the second set the flame traveled from the closed end toward a paper diaphragm that "upon ignition broke and gave a vent for the burned gases." The authors have repeated both sets of experiments and confirmed both results; the figures obtained. were 5.28 percent for propagation upward away from the open end and 5.01 percent for upward propagation in the same vessel toward the open end. However, there was a great difference between the appearance of the limit flames in the two tests. In the first they appeared, after traveling about 12 inches, to be spreading from side to side of the vessel with a strongly convex front and to travel at uniform speed; in the second the flame was apparently not continuous from side to side but consisted of innumerable vertical streaks of flame, traveling much faster and evidently

a turbulent mixture. It was difficult to be lare that the latter flame could travel indefinitely and not be extinguished. In the former experiments the flame traveled into quiescent gas; in the latter the flame traveled into gas that had considerable motion on account of upward expansion of the heated gas. Hence, the conclusion is that, in a wide space, the lower limit of methane in air saturated with water vapor at laboratory temperature is 5.3 percent methane, but that, if the flame is traveling upward from the closed to the open end of a vessel in gas which is therefore in motion, it may travel at least 6 feet when the proportion of methane is not less than 5 percent. Furthermore, in certain circumstances "the flames of mixtures containing 5.3 to 5.6 percent of methane are very sensitive to extinction by shock" (63).

The higher limit of methane in air saturated with water vapor has been determined in a glass tube 7 feet in length and 10 inches in diameter to be 13.87 percent methane (68). This figure may be taken as correcting an earlier and higher estimate (64) based on observations in short, wide vessels and long, narrow vessels.

In a similar vessel with a paper release at the top equivalent to an open end, the higher limit was 15.2 percent under the conditions of movement imparted to the gases (45).

Downward Propagation of Flame.—In a large box nearly 6 feet long and 12 inches square in section the limits with downward propagation of flame in a quiescent mixture were 5.75 and 13.6 percent methane; when the box was closed at the top and open at the bottom, so that motion was imparted to the mixture by the expansion on burning, the lower limit with downward propagation was 5.45 percent  $(4\delta)$ .

Horizontal Propagation of Flame.—In the same box the lower limit with horizontal propagation was 5.55 percent methane. The position of the open end, whether behind or ahead of the flame, was not stated (45).

In a horizontal glass cylinder 7 feet in length and 10 inches in diameter the limits with propagation throughout the length of the tube from open to closed end were 5.42 to 14.03 percent methane. The mixtures were only partly saturated with water vapor; if completely saturated, the higher limit would be reduced somewhat, probably to a value not exceeding 13.87 percent methane—that with upward propagation in the same vessel (68).

Observations in Small Vessels.—Numerous observations have been made of the limits of methane in small vessels. On the whole, the results are fairly consistent, as shown by tables 11 to 14 when allowance is made for variation in experimental conditions. Outstanding discrepant figures are not quoted here, because they have been explained as due to faulty experiment or faulty interpretation. For example, in at least one research it is certain that the mixtures of methane and air were not homogeneous; in another (27S) the observation of a small pressure change on sparking was erroneously interpreted as an indication of fammability; in a third (232) the flame speeds in a series of flammable mixtures of methane and air were extrapolated to zero speed, the corresponding composition being taken as the limit of flammability—an error, because a "limit" mixture has a flame speed that is far from zero. Many of the older figures are omitted because they are but rough approximations compared with more recent results, with which, however, they are not at variance.

A recent series of experiments in narrow tubes has, however, given some anomalous results, not yet explained. In a 2-cm.-diameter tube 60 cm. long, the limits were normally 5.40 and 13.72 percent; but, after the tube had been cleaned with chromic acid, washed, dried, and evacuated to 0.001 mm., the limits observed were 4.70 and 12.86 percent. An extended series of experiments was then made with a "natural gas" containing 94 percent of methane and 0.5 percent of "various hydrocarbons." Tubes 2.5, 2.0, 1.5, and 1.0 cm. in diameter were used, and both limits were determined for upward and downward propagation of flame. The "clean-tube" limits were always lower than the corresponding "normal-tube" limits, the difference being independent of tube diameter

for both limits (downward propagation) and for the higher limit (upward propagation). It is difficult to explain a "wall effect" that is independent of tube diameter (264).

Upward Propagation in Small Vessels.—Table 11 shows the limits with upward propagation of flame in mixtures of methane and air in the smaller vessels. It is evident that the limits found in wide vessels open behind the flame— 5.3 and 13.87 for gases saturated with water vapor-are not appreciably narrower in open tubes 5 cm. in diameter. In closed tubes, however, the higher limit is greater than in open tubes of equal diameter. This is explained by the observation that increase of pressure raises the higher limit; enough pressure to affect the limit is developed in closed tubes in the earlier stages of propagation, while the flame is still assisted by the initial impuse from the source of ignition. This explanation is confirmed by a comparison of two experiments in tubes of the same diameter (5 cm.) but of very different lengths. The shorter tube gave a greater higher-limit figure than the longer tube, because the pressure must rise faster and to a greater quantity in the shorter tube.

TABLE 11.—Limits of flammability of methane in air, with upward propagation of flame in tubes

| Dimensions of tube, cm.                                                                    |                                                                                                     | Bining and                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Limits, percent                                                                                                                                     |                                                                                                        | Content of    | Bafarance                                                                                        |

Horizontal Propagation in Small Vessels.— Table 12 shows the limits with horizontal propagation in the smaller vessels. The limits for closed tubes are narrowed appreciably by reducing the diameter of the tube to 2.5 cm. In open tubes the limits meet when the diameter of the tube is reduced to 0.45 cm. Flame is not propagated, except for a short distance from the source of ignition, along a tube 0.36 cm. in diameter.

Downward Propagation in Small Vessels.-Table 13 shows the limits with downward propagation of flame in the smaller vessels. The limits throughout are somewhat narrower than those found in the largest vessel for the same direction of propagation.

Propagation in Spherical Vessels.—Table 14 shows the limits for propagation of flame throughout mixtures of methane and air in closed spherical vessels of various sizes. The

# . LIMITS OF INDIVIDUAL GASES AND VAPORS

| Dimensions of tube, cm.                                                                  |                                                                                                            | Limits, percent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                               | percent                                                                                                           | Contract of                                                                                                                        | <b>D</b> ./                                                                                                        |

limits become somewhat narrower as the size of container is decreased and generally correspond more nearly with the limits for downward propagation in tubes than with those for either horizontal or upward propagation.

4

All Directions of Flame.—Figure 15 shows the lower limits of methane in a tube 2.25 cm. in diameter and 125 cm. in length, open at the firing end and inclined at various angles. As the direction of flame is changed from vertically upward to vertically downward, the increase in the lower limit is proportional to the change of angle over the range 90° to about 50° and to the change in sine of the angle from 50° to  $-90^{\circ}$  (110).

FIGURE 15.—Lower Limit of Methane for Various Directions of Propagation of Flame in a Tube 2.25 Cm. in Diameter.

Influence of Turbulence and Streaming Movement on Limits of Flammability.—When a small fan was rotated rapidly enough but not too rapidly in methane-air mixtures contained in a 4-liter globe, the lower limit of methane was 5.0 percent compared with 5.6 percent observed for quiescent mixtures in the same vessel. If the turbulence was too violent, however, even a 5.6-percent mixture did not propagate more than a short tongue of flame (33, 350).

A streaming movement of the gas mixture produces similar effects on the lower limit. At a speed of 35 to 65 cm. a second (69 to 128 feet a minute) flame was propagated in a 5.02-percent methane-air mixture but not at any speed in a 5.00-percent mixture (286). Hence, under appropriate conditions of movement of the gas mixture, the lower limit of methane is 5.0 percent. The same figure was obtained when movement of the mixture was produced by expansion caused by its own combustion in experiments on the propagation of flame from closed to open end of a large vessel (p. 137).

Reference may be made to observatious of the effect of turbulence, in somewhat different cir-

cumstances, on the lower limit of natural gas in air (p. 115).

Influence of Pressure.—No measurable change in the limits of methane in air could be discovered, either when the pressure was varied between 753 and 794 mm. (225) or, in the lower limit for upward propagation of flame, when the pressure was varied from 1 to 2.9 atmospheres in a vessel of 11.3 liters capacity (211).

An interesting comparison has been made of the effect of change in pressure from 1 to 6 atmospheres on the limits with downward and horizontal propagation in tubes 2 cm. in diameter (235, 277). With downward propagation, the limits change steadily from 6.00 and 13.00 percent at 1 atmosphere to 6.40 and 14.05 percent at about 6 atmospheres. With horizontal propagation, the lower limit remained nearly constant (5.6 percent) over this range of pressure; the higher limit rose steadily from 13.31 percent at 1 atmosphere to 16.12 percent at about 6.5 atmospheres. In these experiments, therefore, the lower limit with horizontal propagation was unchanged, but that with downward propagation increased

# LIMITS OF INDIVIDUAL GASES AND VAPORS

activity with increasing pressure. The higher later with horizontal propagation increased me rapidly than that with downward propgation. (For an interpretation see, p. 4).

The limits observed under very high pressures (14, 17, 324) are shown in figure 16. One series a higher limits (51) is omitted, because it starts with too low a figure (10.65 percent) for l atmosphere pressure. The rapid increase in the higher limit is remarkable. The differences a the three series of results are to be ascribed to differences in experimental method and interpretation. Experiments almost of necessity had to be conducted in small vessels, but the results doubtless are a fair indication of the possibilities of explosion in larger vessels holding mixtures of compressed gases.

Figure 17 shows limits at less than atmospheric pressure and at various temperatures, in a tube 2 cm. in diameter and 50 cm. in length, with downward propagation of flame (235). The curve for 20° C. shows much wider limits at low pressures and extends to much lower pressures than those observed in an older series of tests (47). The more recent results were ined with a stronger igniting spark; sparks

will ignite a flammable mixture at normal pressures may be much too weak to ignite it at low pressures.

Experiments in a wider tube, 5 cm. in diameter and 50 cm. in length, compare the limits for different directions of propagation of flame at pressures less than atmospheric (277). The curves for these limits are plotted in figure 18. Data were not obtained for upward propagation at the lower limit because, in the rather short vessel used, the issue was confused by the large "caps" of flame above the igniting spark. A complete curve for horizontal propagation in a tube 4.5 cm. in diameter and 120 cm. in length has, however, been obtained (125). It shows a small abnormality on the higher-limit side at 150 to 200 mm. pressure, where "green flames" were observed. A complete curve for propagation in a burette has also been obtained (86). Other curves for propagation in narrow tubes show abnormalities on either the lower- or higher-limit side at reduced pressures (99).

Influence of Temperature.—Several older observations have been criticized unfavorably on the grounds that the mixture underwent partial combustion in the heated experimental vessel before it was tested and its composition was thereby altered enough to affect the results. The less exceptionable results are compared in figure 19, which shows lower and higher limits up to temperatures at which spontaneous inflammation of the mixture was almost instan-

FIGURE 16 .- Effect of Pressures Above Normal on Limits of Methane in Air.

LIMITS OF INDIVIDUAL GASES AND VAPORS

FIGURE 19.—Limits of Flammability of Methane in Air (Downward Propagation), Showing Influence of Temperature.

taneous. In each series the direction of propagation of flame was downward; the other conditions are indicated on the figure, together with the reference numbers. As will be noted, the range of flammability is widened considerably at both limits by increase of temperature, but ordinary variations of atmospheric temperature have an insignificant effect.<sup>6</sup>

Figure 17 shows the temperature effect at pressures less than normal.

The differences between the results of the more all the sets of tests in figure 19, although small

ower limits and not very large for higher i. s, are real and must be due to the use of different apparatus. For higher limits the length of tube used seems to be the determining factor, as shown by series 2 and 4 (fig. 19) with tubes of nearly the same diameter. Hence all the results are relative to the apparatus used and do not show the influence of temperature on limits defined as a property of the gas mixture alone. The results may, however, be taken as an indication of the effect of temperature on the true limits.

An unconfirmed observation is that, although the limits in moist methane-air mixtures are widened by increase in temperature, the lower limit as well as the higher limit is much raised by increase of temperature when the mixtures are dried with phosphorus pentoxide (297).

Low Temperatures.—At the temperature of liquid air the lower limit of methane with downward propagation of flame in a tube 2.5 cm. in diameter and 40 cm. in length, open at the firing end, is  $7.3 \pm 0.3$  percent (110). In

<sup>&</sup>lt;sup>3</sup> Formulas to express the influence of temperature on the limits have been given (225) for the range  $0^{\circ}$  to  $40^{\circ}$  C. They are: Lower limit, n=n=0.0042t; hence limit, n'=n'=+0.0030t.

the same circumstances, but at room temperature, the limit is 6.1 percent.

Influence of Pressure at Various Temperatures.—The curves of figure 17 show the limits of flammability of methane-air mixtures at 20°, 250°, and 500° C. at all pressures below atmospheric. The limits were observed in a closed tube 2 cm. in diameter and 50 cm. in length (235).

A mixture of 2.1 percent methane in air was ignited by sudden compression to 80 atmospheres pressure, which produced a temperature of 705° C., and a mixture of 55 percent methane at 118 atmospheres and 540° C. (87).

Influence of Impurities.—The lower limit of methane in air, with downward propagation of flame, was raised about 1.3 percent by iron carbonyl (0.03 cc. liquid vaporized per liter). The higher limit was reduced from 13.0 to 10.5 percent by the same quantity of iron carbonyl (325).

# METHANE IN OXYGEN

The limits of methane in oxygen, with upward propagation of flame in a 2-inchdiameter tube open at its lower end, are 5.15 and 60.5 percent (138).

Table 15 gives other determinations of the observed limits of methane in oxygen.

Upward Propagation of Flame

Influence of Pressure.—The limits of methane in oxygen were not appreciably narrowed until the pressure was reduced below 150 mm. A moderately strong igniting spark was used

والمراجع والمتحج والمحاد مروم المراجع

(65). With a stronger spark the limits did not coincide until the pressure was reduced to 10 mm. (SO). A curve has been obtained for results in a burette (SO).

The higher limit is increased by an increase of pressure above atmospheric. One observation (330), incidental to other work, is that, at 10 atmospheres pressure, a mixture containing 71 percent methane slowly propagated flame. In a small bomb (58) the higher limit rose rapidly from 58.4 percent at 1 atmosphere to 81.7 percent at 60 atmospheres, then slowly to 84 percent at about 145 atmospheres; however, the mixtures contained about 4.5 percent nitrogen, and the limits would be somewhat higher in pure oxygen. Combustion was far from complete in such mixtures under moderately high pressure.

Influence of Temperature.—In a 35-cc. closed bulb the limits were 6.2 and 57.1 at 15° C. and 5.1 and 57.8 at 300° C. (297).

Influence of Temperature at High Pressures.—As the temperature is raised, the pressure required to make certain mixtures of methanc and oxygen flammable decreases. For example, the pressure limit of a mixture containing \$1.7 percent methane at atmospheric temperature was 60 atmospheres, but at 332° C. it was only about 21 atmospheres (58). Curves that show the higher limit at elevated temperatures and pressures are given in the original paper.

# METHANE IN OTHER ATMOSPHERES

Atmospheres of Composition Between Air and Pure Oxygen.-The limits of methane in mixtures of nitrogen and oxygen richer in oxygen than ordinary air have been found as follows: (1) In a closed globe 2.5 liters in capacity the lower limit rose regularly from 5.8 percent in air to 6.0 percent in oxygen (267); (2) in a horizontal glass tube 2.5 cm. in diameter, open at the firing end, the lower limit fell from 5.3 percent in air to 5.7 percent in oxygen, and the higher limit rose linearly from 13.3 in air to 59.2 in oxygen (189); (3) in a closed tube 1.9 cm. in diameter the lower limit with downward propagation of flame rose regularly from 6.15 percent in air to 6.45 percent in oxygen. The higher limit rose from 12 percent in air to 38 percent in a 62-percent oxygen mixture and 52 percent in a 95-percent oxygen mixture (323).

Atmospheres of Air and Nitrogen (Air Deficient in Oxygen).—Large-scale experiments with mixtures of methane, air, and nitrogen have been made in a tube 7 feet in length and 10 inches in diameter, with upward propagation of flame from the open end of the tube; the mixtures throughout were at atmospheric pressure and were saturated with water vapor. The range of observations shown in figure 20

34.5 t

FIGURE 20.—Limits of Flammability of Methane in Mixtures of Air and Nitrogen (Experiments in Large Vessels).

covers all compositions from air to mixtures in which the amount of oxygen is too small for flame propagation, regardless of the amount of methane present. The abscissas represent the "atmosphere" in each mixture of air and nitrogen; for example, 25 percent "additional nitrogen" means that the "atmosphere" used for the observations was composed of 75 percent air and 25 percent nitrogen. Along the top of the diagram the corresponding percentages of oxygen in the atmosphere may be read. It is wident that no mixture of methane is flammable at "inary temperatures and pressures when the usphere contains less than 12.8 percent oxyge... and the remainder is nitrogen (68).

The results of observations made in smaller apparatus are shown in figure 21. In a 5-cm. tube, with upward propagation of flame in a dry mixture, the limits nearly coincide with those plotted in figure 20. The three curves that show narrower limits represent experiments in various types of apparatus with downward propagation of flame. One curve shows greater values over part of the higherlimit range; the values were obtained in a closed vessel in which the pressure rose considerably during the inflammation, and increase of pressure is known to increase markedly the higher limit of methane. The limits of these mixtures with downward propagation of flame in a closed tube 2.2 cm. in diameter (341) and in a closed glass bulb 6.5 cm. in diameter (209)have also been determined.

For some purposes the results are more useful when expressed (62) as in figure 22. For example, it cannot be deduced from figure 20 without calculations, that the mixture

|          | Percent |
|----------|---------|
| Methane  | 12      |
| Oxygen   | 2       |

÷

cannot form an explosive mixture with air, whatever the proportions used, whereas the mixture

|          | 7-61.24119 |
|----------|------------|
| Methane  | 9          |
| Oxygen   | 12         |
| Nitrogen | 79         |
|          |            |

although not itself explosive, may form a series of explosive mixtures with air. Figure 22 gives this information at a glance.

Explanation of Figure 23.—Figure 23 explains figure 22. The straight line AD (fig. 23) represents the composition of all mixtures of methane and pure air that contain up to 20 percent methane. No mixture of methane and air can fall above this line, and all mixtures of methane,

air. and nitrogen must fall below it. The line BE is the line of lower limits of flammability of methane and CE the line of higher limits. As the oxygen content falls, BE and CE approach each other until they meet at E. No mixture which contains less oxygen than that corresponding with E is explosive per se, but all mixtures in the area BEC are within the limits of flammability and are therefore explosive.

Next consider any mixture to the right of the line CEF; for example, the mixture represented by the point G. Join GA. Then GA represents the mixtures formed, in succession, as G is diluted with air. Because GA passes through the area BEC the mixture, as it is diluted with air, becomes explosive and remains so as long

FIGURE 21.—Limits of Plammability of Methane in Mixtures of Air and Nitrogen; Comparison of Results Obtained in Smaller Vessels.

LIMITS OF INDIVIDUAL GASES AND VAPORS

Figure 22.—Relation Between Quantitative Composition and Flammability of Mixtures of Methane, Air, and Nitrogen.

as its composition is represented by any point on HJ.

It will now be clear that the position of FEis exactly defined by drawing a tangent from A to the curve BEC and extending the tangent to meet the axis of abscissas in F, because the line joining any point above and to the right of FE to A must pass through BEC, while the line joining any point below and to the left of FE to A must fail to pass through the explosive region BEC. FE is therefore the boundary of those mixtures capable of forming explosive mixtures with air.

Figure 22 shows clearly that any mixture of methane and nitrogen that contains more than about 14.3 percent methane can form explosive mixtures with air. If oxygen is present a prespondingly smaller amount of methane uffices.

Mixtures of methane, nitrogen, and oxygen that are represented by any point in the area *DCEF* of figure 23 can form explosive mixtures when mixed with air in suitable proportions. If it is of interest to know what these proportions are—and if there is a wide range of possible explosive mixtures the danger is so much the greater—then they can be found from the following considerations:

Suppose the mixture of methane, nitrogen, and oxygen is represented by the point G in the area *DCEF*, then the straight line *GA* represents all possible mixtures of the original mixture and air. As the original mixture is diluted step by step with air, the composition of the new mixture is represented by points farther and farther along *GA*. The air mixture first becomes explosive per se at the point H, where *GA* crosses *EC*. The higher limit of the original mixture is defined by this point; the lower limit of the original mixture is defined by the point J, at which the *GA* cuts *EB*.

The ratio AH: HG is the ratio of original mixture to fair in the upper-limit mixture, and the ratio AJ: JG is the ratio for the lowerlimit mixture. Hence the limits of flammability of the original mixture are given (in percentages) by 100 AJ/AG (lower limit) and 100 AH/AG (higher limit) (62).

All Atmospheres of Oxygen and Nitrogen.— Limits of methane in these atmospheres have been determined with downward propagation of flame in a 1.7-cm.-diameter tube (345).

Atmospheres of Air and Water Vapor.—Observations that show the small difference in the limits of methane in dry air and in air saturated with water vapor at laboratory temperatures are quoted under Effect of Small Changes in Atmospheric Composition (p. 3).

The effect of large amounts of water vapor on the limits of methane in air is shown in figure 24. The determinations were made in a tube 3 feet in length and 2 inches in diameter, with upward propagation of flame at atmospheric pressure during propagation (67). For each experiment the tube was heated to the temperature necessary to maintain the required amount of water vapor. Hence, most of the observations were made at temperatures above normal. Had it been possible to experiment at normal temperature, the curve probably would have been a little to the right of the carbon dioxide curve over the lower-limit range and at the nose, but the two curves would have coincided over most of the higher-limit range.

Similar experiments have been made in a closed 350-cc. spherical vessel with a "natural gas" containing 97 percent methane, 3 percent ethane. Similar results were obtained, with somewhat smaller limits, which met at about 6.3 percent gas in a mixture containing about 30 percent of water vapor (368).

Atmospheres of Air and Carbon Dioxide.— Figure 25 shows the limits of methane in mixtures of air and carbon dioxide saturated with water vapor. The tests were made in a tube 7 feet in length and 10 inches in diameter, with

Colo., and Tintic and Part City, Utah, districts, as well as in numerous other metal-mining regions.25 26 27 Carbon dioxide is a constituent of blackdamp, and traces of it (0.03 percent) are always present in normal air.

One-half of 1 percent (0.5 percent) of carbon dioxide in normal air causes a slight increase in the lung ventilation: a man exposed to this percentage of carbon dioxide will breathe a little deeper and a little faster than when in pure air. If the air contains 2 percent of carbon dioxide, the lung ventilation will be increased about 50 percent; if 3 percent, about 100 percent; if 5 percent, about 300 per cent, and the breathing is laborious; and 10 percent cannot be endured for more than a few minutes.28 Carbon dioxide in the resulties of feets when the oxygen content remains about normal and the may is at rest. Moving around or working would naturally increase the symptoms, and they would be much more dangerous than when a man is resting.

Solid (dry ice) or liquid carbon dioxide sublimes or vaporizes at 109.3° F. below zero.<sup>5</sup> Liquid carbon dioxide is employed in a special permissible cartridge for blasting coal.<sup>30</sup> and dry ice has been used as a source of inert gas in fighting mine fires.

# METHANE (CH.)

Methane, also known as marsh gas, is one of the chief constituents of firedamp. It is colorless, odorless, tasteless, no poisonous, and flammable. As stated, methane is odorless; but, because it may be accompanied by other gases that are odorous, the mixture may have a distinct odor. Its common occurrence in the old workings of names. where the air may be musty from decaying timbers and other in parities, has caused many mining men to believe that methane has an odor. The specific gravity of methane is 0.5545,<sup>33</sup> and its weight per croic foot at sea-level pressure and 70° F. is 0.042 pound. Methane is found in almost all coal mines and occasionally in metal and other types of mines and in tunneling operations. In coal mines it may issue from the cleats or cracks of the coal, from "blowers" or "feeders," or from overlying or underlying strata and often is released in large amounts from the coal when irregularities, such as clay veins, "horsebacks," or faults, are encountered. In metal mines and in tunnel driving, n.ethane frequently is found when carbonaceous shales are penetrated and occasionally is present by infiltration into metal mines at contacts or near carbonaceous rocks. Methane may be generated by the action of certain bacteria on organic matter, such as mine timber, and explosions have been caused by accumulated methane from this source while flooded mines were being unwatered. The liberation of methane from

### SOURCES, CHARACTERISTICS, AND PLYSICLOGICAL FECT

Then

the strata in mines may be a steady flow of a sudden out surst. present, it is usually found near the mine coof or in high places but, after becoming thoroughly mixed with aid it will be found unif rmly distributed across any cross section of a poving air current and will not separate or stratify from still air. Mechane may be letected with a flame safety lamp (preferably of the permissible type and by various other approved detecting devices. Me have has no : pecific physiological effect upon man, but enough may accumulate i i mine orkings to dilute the oxygen of the air and pi-duce atmospheres detrient in oxygen. Deaths from asphyxiation have resulted from mer unknowingly entering high concentrations of methane.

The common occurrence of methane and ts explosibilit; when a ixed with air are directly responsible for numerous name disasters. Air that contains 5 to 15 percent of the methan- $^{32}$  and 12.1 percent or nore  $\alpha$  will explode if ignited.<sup>33</sup>

Methane is not the only cause of mine explosions. Elected lust, except anthracite, suspended in air is explosive, but coal dust explosions are propagated more rapidly and more readily when methode is present, even in percentages much below the lower explosive mit. Tests conducted in the Experimental mine of the Bureau of Mines show that, under the most favorable conditions as to diffusion of gas, point of ignition, and placement of coal dust a uniform gashir musture of 146 cubic feet, containing approximatel 13 cubic fee of methane (about 9 percent of the mixture), if ignite l, is sufficient to initiate a general explosion." Although the conditions under which these jests were conducted are rarely found in comm-relational mines, these experiments clearly indicate the danger of ign ting even a small quantity of methane in the presence of coal dust.

Bureau of Mines engineers believe that 200 cubic feet or possibly less, of an explosive methane-air mixture can precipita e a general explosion under conditions usually found a mines, if the mixture is ignited in the presence of coal dust. The oncentration of methane, therefore, should be kept as low as possible by proper vertilation. It has been recommended that the safest practice is to present the accumulation of explosive mixtures and to keep the methan contens of every air current below 0.5 percent at all times."

## CLASSIFICATION OF COAL MINES IN RESPECT TO METHANE THERATION

The Bureau of Mines believes that all coal mines are potentially gassy, but for purposes of administration i respect to prevention of explosions and fires the Federal Mine Safety Code (ar the V, sec. 10a) contains the following:

If and when a mine, subject to Title II of the Federal Coal Mire Safety Act, is classified as a gassy mine under the provisions of Title II of the Act. ach

<sup>106</sup>Ow which an explosion is imposunt is represent.

| 70 to 80                   | Weak pulse and slowed respiration, respiratory failure, and death.                                                  |

The symptoms decrease in number with the rate of saturation. If suddenly exposed to high concentrations, a man may collapse before he experiences any warning symptoms. The rate at which a man is overcome and the sequence in which the symptoms appear depend on several factors-the concentration of gas, the extent to which he is exerting himself, the state of his health and individual susceptibility. and the temperature, humidity, and air movement to which he is exposed. Exercise and high temperature and humidity, with little or no air movement, tend to increase respiration and heart rate and consequently result in more rapid absorption of carbon monoxide. Under conditions that may be encountered in mining, interest centers mainly on the symptoms of "acute" carbon monoxide poisoning that may develop rather suddenly upon exposure to high concentrations of the gas. However, prolonged exposure to low concentrations or carbon monoxide that do not produce immediate, serious effects (sometimes referred to as "chronic" exposure or poisoning) may result in a continual feeling of tiredness, headache, nausea, palpitation of the heart, and sometimes mental dullness.

In severe cases of carbon monoxide poisoning that result in prolonged unconsciousness, with accompanying depletion of the normal supply of oxygen to the body tissues, permanent damage may be suffered, particularly by the brain, so that the victim, although surviving, may do so with impaired mind, suffering loss of memory and paralysis or sensory defects.<sup>39</sup> Such effects are not caused specifically by the carbon monoxide but rather by the prolonged lack of oxygen

m geiss 11 .coognized maximum allowable concentration<sup>41</sup> for posure to air containing carbon monoxide and with en content is 0.01 percent (100 parts of carbon monoxide parts of air, by volume). Somewhat higher concentraa o-hour normal ox per millic tions may be considered allowable for shorter periods of exposure. For example, in the ventilation of vehicular tunnels, the maximum is generally et at 0.02 percent, as based upon the exposure of traffic officers in ternate 2-hour periods over an 8-hour shift.

# HYDROGEN SULFIDE (H2S)

Hydrogen sulfide-called stinkdamp from its odor, which resembles that of rotten eggs-is a colorless gas and is usually a product of the decomposition of sulfur compounds.<sup>42</sup> It may be produced also by burning explosives containing sulfur and may be liberated in using black blasting powder or dynamite in blasting sulfide ores. Hydrogen sulfide is also found in large and extremely toxic amounts in the initial gas and oil from certain fields, and it is frequently found in gypsum mines. Occasionally, though rarely, it has been found issuing with methane from gas blowers or feeders in coal mines,<sup>48</sup> and in numerous instances it is carried into mine workings by water, in which it is easily dissolved. Enough has been found in coal mines during normal conditions to cause severe eye irritation. Ine specific gravity of hydrogen sulfide is 1.1906,4 and its weight per cubic foot at sea-level pressure and 70° F. is 0.089 pound. Air that contains 4.3 to 45 percent of hydrogen sulfide will ignite when subjected to ordinary flames and will explode.45 Hydrogen sulfide is very poisonous; wherever it exists the possibility of poisoning is

The generally recognized maximum allowable concentration of hydrogen sulfide in the air of working places is 0.002 percent by volume (20 parts of hydrogen sulfide per million parts of air) during an 8-hour exposure.47

Hydrogen sulfide acts mainly as an irritant in subacute poisoning caused by concentrations up to about 0.07 percent; and irritation of the eyes, ranging from mild to severe depending on the extent and intensity of exposure, is the most common symptom. In higher concentrations acute poisoning occurs, which is far more dangerous than the subacute effects, as systemic poisoning results, which may have a general action on the nervous system and cause almost immediate respiratory paralysis and death. Experiments have shown that dogs exposed to concentrations of hydrogen sulfide ranging from 0.1 to 0.2 percent collapsed and ceased breathing in about 1 minute. If the dogs were withdrawn from the contaminated atmosphere at once and given artificial respiration they were revived and in a matter of minutes showed no ill effects of the experience. This demonstrates the need for immediate rescue, removal to fresh air, and resuscitation of persons overcome by hydrogen sulfide, although it must be emphasized that many persons have lost their lives in attempting to rescue victims of hydrogen sulfide poisoning by entering the contaminated atmosphere without respiratory protective equipment. If there is any evidence or suspicion that hydrogen sulfide is present, respiratory protective equipment should be worn by persons entering the affected area. Although hydrogen sulfide has a distinctive odor, the sense of smell cannot be relied upon as a means of detection because after 1 or 2 inhalations the olfactory nerves become paralyzed and the odor of hydrogen sulfide can no longer be detected.

In addition to eye irritation, low concentrations of hydrogen sulfide produce symptoms of subacute poisoning, such as headache, dizziness, excitement, nausea or other disturbances of the storach and intestinal tract, dryness and sensation of pain in the nose, throat, and chest, and coughing.<sup>48</sup> The acute effects of high concentrations of

# SOURCES, CHARACTERISTICS, AND PHYSIOLOGICAL EFFECTS

hydrogen sulfide, as described above, are immediate and decidedl dangerous.

# ETHANE (C2H3), PROPANE (C3H3), AND BUTANE (C4H10)

Ethane, propane, butane, and other heavier (higher molecula weight) members of the methane or paraffin-hydrocarbon series ar components of natural gas but are not found normally in coal mines except possibly in traces. The specific gravity of ethane is 1.0493 of propane 1.5625, and of butane 2.0100,49 and the weights per cubi foot at sea-level pressure and 70° F. are 0.079 pound for ethane, 0.11 pound for propane, and 0.151 pound for butane. These gases ar sometimes present in small quantities in association with methane in gases from mine fires and explosions. They tend to increase the ex that or unitary, because their lower limits of flammability are less that enough to be dangerous or even to be detected readily. However when over 1 percent of these "higher hydrocarbons" is found in mine, leakage from a gas or oil well is suggested. Air that contain 3.2 to 12.5 percent of ethane is explosive. For propane-air mixture the corresponding limits are 2.4 to 9.5 and, for butane-air mixtures 1.9 to 8.4 percent.<sup>5</sup>

# OXIDES OF NITROGEN (NO, NO2, ETC.)

Oxides of nitrogen are formed in mines by burning, by afterburning and, under certain conditions, by detonation of high explosives. The are also components of the exhaust of diesel and gasoline engines and are formed by the reaction of atmospheric oxygen and nitrogen in the air in close proximity to electric arcs and sparks. Oxides of nitrogen are produced also by burning or decomposition of nitrates and nitrated materials. Nitrogen forms several oxides— $N_2O$ , NO, NO<sub>2</sub>,  $N_2O_4$ ,  $N_2O_3$ , and  $N_2O_5$ . Of these, only nitrous oxide ( $N_2O$ ) is harmless and is sometimes used as an anesthetic. The others are toxic. The most commonly occurring toxic oxides of nitrogen are nitric oxide (NO) and nitrogen dioxide, which occurs in two forms (NO2 and N2O4), depending on the existing temperature. Nitric oxide does not exist in significant amount in the air, as in the presence of moisture and oxygen it is oxidized to the dioxide. Therefore, when air samples are analyzed for oxides of nitrogen the results usually are reported in terms of nitrogen dioxide  $(NO_2)$ , as such designation gives proper evaluation of the toxic properties of the atmosphere. Nitrogen dioxide is brownish red but is not visible, particularly in dimly lighted places, in low concentrations, which nevertheless may be quite toxic. Oxides of nitrogen, in their several forms, are believed to contribute to the powder-fume odor that follows blasting with high explosives.<sup>51</sup> The specific gravity of nitrogen dioxide is 1.5894,52 and its weight per cubic foot at cea-level pressure and 70° F. is 0.119 pound.

#### INTRODUCTION

This report is based on an investigation made by the writers, who through the Director of the Bureau of Mines were assigned by the Assistant Secretary--Mineral Resources, Department of the Interior to undertake a full scale investigation of the explosion. As part of the investigation, survivors, many employees, and officials were interrogated informally to secure information on the explosion, to ascertain events prior to the explosion, and to learn of practices which might have set the stage for the disaster. This hearing was conducted as a result of a request to the Honorable George Dewey Clyde, Governor of Utah, from Assistant Secretary John M. Kelly, Department of the Interior (see Appendices A, B, and C).

A gas explosion occurred in the Cane Creek mine about 4:40 p.m., Tuesday, August 27, 1963. Twenty-five men were underground at the time; 18 died from the flame, forces, or asphyxiation. Three men erected a barricade near the face of 2 south and died behind it. The other 7 men erected a barricade in 3U drift; 2 of these men left the barricade and traveled to the shaft station where they were met by a rescue crew and brought to the surface at 11:55 a.m., August 28, about 19 hours after the explosion occurred. The other 5 men remained behind the barricade until a recovery crew contacted them and they reached the surface without assistance at 6:30 p.m., August 29, about 50 hours after the explosion. A surface employee received minor injuries and was hospitalized. The names of the victims, survivors, and the injured surface employee, their ages, marital status, occupations, and number of dependents are listed in Appendices D and E of this report.

Bureau of Mines investigators believe the explosion originated in the shop area where an explosive mixture of combustible gases was ignited by electrical arcs or sparks, open flame, or heated metal surfaces. Forces of the explosion extended to the shaft station, up the shaft to the surface, and throughout the greater part of 2 south and 3U drifts.

#### GENERAL INFORMATION

The Cane Creek mine, Potash Division of the Texas Gulf Sulphur Company is in Grand County about 20 miles southwest of Moab, Utah, by road, and is reached by paved State Highway 279. The mine is served by the Denver and Rio Grande Western Railroad, and is being developed on State and Federal land.

Officials of the Texas Gulf Sulphur Company are:

| Claude O. Stephens     | President and Chief Executive Officer,<br>New York, New York          |
|------------------------|-----------------------------------------------------------------------|
| Dr. Charles F. Fogarty | Senior Vice President, New York,<br>New York                          |
| Frank E. Tippie        | General Manager, Moab, Utah                                           |
| J. F. Henderson        | General Superintendent and Acting Plant<br>Superintendent, Moab, Utah |
| K. J. Kutz             | Mine Superintendent, Moab, Utah                                       |
| R. J. Ferranti         | Assistant Plant Superintendent,<br>Moab, Utah                         |

Officials for Harrison International, Incorporated dealing with the Cane Creek project are:

| Nathaniel Harrison | Chairman, Miami, Florida        |
|--------------------|---------------------------------|
| Patrick Harrison   | President, Miami, Florida       |
| Norman Harrison    | Project Manager, Moab, Utah     |
| George E. Smith    | Chief Engineer, Moab, Utah      |
| A. W. Trenfield    | Mine Superintendent, Moab, Utah |

The mine is in the development stage and production of ore has not been started. A contract for the sinking of the shaft and driving the development drifts in waste to the ore body was given to the Harrison International, Incorporated, of Miami, Florida, and practically all work being done at the time of the explosion was by the contractor. Likewise, most underground employees were the contractor's. The work schedule was 7 days a week, 3 shifts a day. The average underground employment for Harrison International, Incorporated was 80 men, divided approximately into 30 men on day shift and 25 men each on swing and graveyard shifts. Engineering and maintenance of some equipment was provided by Texas Gulf Sulphur Company. There were many occasions for personnel of the Texas Gulf Sulphur Company to enter the mine, such as for ventilation checks, temperature readings, gas testing, and for collecting other pertinent data. Texas Gulf men worked underground in the shop regularly on 2 shifts daily.

The mine is opened by a circular shaft 22 feet in diameter, inside the concrete lining. The shaft is 2,789 feet in depth; the station is 2,712 feet below the surface. Four sinking buckets, equipped with crossheads and rope guides, were used in the shaft sinking operations and are now used to hoist muck and handle men and materials. Two main development drifts, designated 2 south and 3U and paralleling each other, were advanced about 2,080 and 3,170 feet, respectively, from the shaft station. The 2 south drift was driven downgrade 10 percent from the No. 1 crosscut, a short distance from the shaft. The 3U drift driven downgrade 14 percent is offset slightly but is a continuation of 1 south drift driven 10 percent downgrade from the No. 1 crosscut for a distance of about 360 feet, then level for a distance of 800 feet to the start of 3U which was driven downgrade 14 percent. The face of 3U was within one or two rounds of intersecting the potash bed, which averages 11 feet in thickness and dips 15 percent northeasterly as determined by test drilling.

Strata over the potash bed is variable and consists of salt and various clastics. The floor is salt.

A regular Federal inspection of this mine was made November 28-29, 1961, when the shaft was at a depth of 840 feet. In addition, four separate investigations of fatal accidents were made by Bureau of Mines personnel prior to the explosion.

#### MINING METHODS, CONDITIONS, AND EQUIPMENT

<u>Mining Methods</u>: Mine projections show that a block system of mining will be followed when the potash bed is reached. Development at the time of this occurrence consisted of driving the two aforementioned drifts, 2 south and 3U. In addition, a ventilation drift was used for a temporary shop and drifts for ore bins and conveyor ways were partly developed (see Appendices G, H, and J).

The presently developed drifts, when driven in salt, were 18 feet wide and 6 feet high on the walls and the back was arched so the center was 8 feet high. When driven in other than salt, the drifts were blasted 17 feet wide allowing for a total of 1-foot sloughing on the two walls. Reportedly, the contractor's plans required that in salt formation the face be undercut its full width to a depth of 1C feet. However, the shift or crew leaders used their judgment concerning depths and widths of the undercuts, rather than follow the stipulated requirements. Undercutting was done only in salt formations.

The salt back was generally self supporting, but rock bolts were used sporadically where necessary. Rock bolts and chain link fencing were installed for support in other than salt back, and steel H-beam arch sets were installed in shales where the back was poor. Rock bolting was as follows: Rock bolt holes,  $1\frac{1}{2}$  inch in diameter, were drilled with compressed-air stopers. The bolts were 6 feet in length and 3/4 inch in diameter. Expansion shells were used to anchor the bolts and the bearing plates were 6 inches square by  $\frac{1}{2}$ -inch thickness. The bolts were tightened with the stoper. Chain link fence used was 25 feet long by 6 feet wide. The sections of chain link fence were held tight against the back by 3 rows of bolts installed widthwise in the drifts, 7 bolts to the row. The bolts were about  $2\frac{1}{2}$  feet apart widthwise and 2 feet apart lengthwise. The chain link fence sections overlapped so that the rows of bolts along the edges caught both sections. Pull tests were not made to test the effectiveness of the bolts nor were torque readings made.

The drifts were developed with mobile loading machines.

<u>Explosives</u>: Blasting was done with 40- and 60-percent dynamite, regular delay detonators, and nonpermissible blasting machines. The detonators were 0 to No. 14 delays with 12-foot long copper leg wires, and the shots were blasted from stations in the drifts. All blast holes were bottom primed, but stemming was not used.

Reportedly, the explosives and detonators were transported from the surface magazines in their original containers to the shaft collar, lowered in the sinking buckets to the shaft station, from where they were transported in Diesel-powered shuttle cars to the storage locations in the various drifts. At times detonators and explosives were transported together.

Explosives and detonators were stored underground in separate recesses along the walls of the drifts, and reportedly underground storage was limited to a 2-day supply. During the investigation, containers of oil and rock bolting materials were stored with the detonators. A wooden detonator box was provided but the lid was open with detonators stacked on the lid. In 3U drift, 2 cases of deteriorated explosives and 3 bags of AN/FO explosives were in the explosives storage area.

According to the contractor's representatives, blasting was about as follows:

When undercutting was done, blast holes were drilled in a pattern about  $2\frac{1}{2}$  feet apart horizontally and vertically in the center of the place and

at lesser distances between the center and the walls. Blast holes in places that were not undercut were drilled on about 2-foot and  $2\frac{1}{2}$ -foot vertical centers at the walls and vertical center line, respectively. Horizontally, the blast holes at the bottom and top were about 4 feet apart. Holes were drilled on about 1-foot centers around the four burn cut holes that were drilled in the center of the face. Blast holes were drilled 10-, 8-, and 6-feet deep depending on whether the strata were considered good, fair, or poor, respectively. Blast holes were fired on shift with men underground.

The cycle of mining called for undercutting (when in salt), drilling, blasting, and loading. However, there were times when the blast holes were charged with explosives while undercutting and drilling were in progress. After the explosion, officials of Harrison International stated that all shots not in salt would be fired from the surface when all men were out of the mine.

Ventilation and Mine Gases: Ventilation of the mine at the time of the explosion was temporary, because only one shaft was available and a dividing partition wall was not yet installed in the single shaft. Intake air was directed into the mine by means of metal tubing. Two sets of 3 Joy Axivane, 40-horsepower fans connected in tandem, were located on the surface near the shaft collar and operated blowing. One set of the fans provided intake air for the 2 south drift, and the other set of fans provided the intake air for 3U drift. The intake air was conducted from the fans through 26-inch diameter spiral steel vent tubing extending from each set of fans down the shaft and along 1 south and 2 south drifts, distances of 200 and 325 feet from the shaft station in 2 south drift and 1 south drift, respectively. At these locations, 36-inch diameter corrugated galvanized metal tubing was connected to the 26-inch tubing and extended into 2 south and 3U drifts.

In an effort to increase the amount of air being delivered to inby ends of the tubing, booster fans of the same size as those on the surface were installed in the 36-inch metal tubing at 900- to 1,050-foot intervals. Such installations are conducive to recirculation of air in the event of damage to and/or leaks in the tubing. Such damage and/or leaks in the tubing would occasionally occur in installation and during movement of shuttle cars in the same drift. Two booster fans were installed in the tubing in 3U drift and one such fan was installed in 2 south drift.

Four 15-horsepower Axivane fans without tubing were installed at electric power load center locations to provide a cooling effect on the load centers by forcing air over or by pulling air past them. Obviously, such installations resulted in recirculation of the air. In addition, a 15-horsepower Joy Axivane fan without tubing was suspended near the back at the beginning of the return air flow through the 3 south shop area to increase air velocity in the shop. To provide a volume of cool air for this fan, compressed air was fed through a 3/4-inch diameter hose into the fan intake and an additional supply of compressed air was released in the shop area through a second 3/4-inch diameter hose. A check curtain was installed in the shop inby the fan, reportedly to prevent smoke from blasting from entering the shop. This check curtain would have made recirculation of air by the fan in the shop inevitable, although shop employees stated the curtain opened somewhat while the fan was operating.

Air readings recorded on a ventilation map by Texas Gulf Sulphur Company were: On August 16, 1963, 14,500 cfm returning along 2 south as determined by smoke cloud velocity tests made about 475 feet inby No. 1 crosscut. The metal tubing extended into 2 south for 1,350 feet inby this point. The end of the metal tubing was about 60 feet from the face and flexible rubberized tubing extended toward the face from that point. On August 19, 1963, 12,500 cfm of air was returning from 3U as determined by smoke cloud velocity measurements made in 3U drift about 850 feet outby the present working face. On August 20, 1963, 15,900 cfm was returning from 3U drift as determined by smoke cloud velocity tests made in No. 1 south about 550 feet inby No. 1 crosscut. The metal vent line was extended to within 125 feet of the face of 3U; flexible rubberized tubing extended from the end of the metal tubing to within 50 feet of the face. Two booster fans were installed in the metal tubing inby the point of the last air measurement.

The temperature readings, recorded in connection with air readings in 3U drift on August 19 and August 20, 1963, were 104° and 100° Fahrenheit, respectively. Temperature readings were not recorded in connection with the air measurement in 2 south on August 19, 1963. Recorded random mine temperatures in 3U drift on August 27, 1963, ranged from 102 to 105 degrees Fahrenheit. A temperature reading of 98 degrees Fahrenheit in the shop was also recorded the same day.

Early during shaft sinking operations, crude oil was encountered, and about 11:00 p.m., on July 31, 1963, four men were burned when combustible gas was ignited in 3U drift. These occurrences were not reported to the Bureau of Mines, but were reported to a state mine inspector. The combustible gas emitted from a rock bolt hole and was ignited when one of the workmen attempted to light a cigarette with the flame from a cigarette lighter; flame flashed throughout the area and flame continued to burn in crevices and the muck pile until the next day. The gas emitting from the hole and muck pile burned until 5:00 a.m., August 1, when the flame was extinguished. It was extremely hot while the gas burned. Following this ignition, examinations for combustible gas were increased, and a "No Smoking" rule was put into effect underground. Following the July 31 explosion, additional flame safety lamps were issued, but questioning of employees revealed that some had not been properly instructed in the use of these lamps.

Also, tests for combustible gas were made by personnel of the Texas Gulf Sulphur Company, using permissible electric methane testers and permissible flame safety lamps. The results of tests were included in memoranda on the subject "Shift Summary" starting on August 5, 1963. Following are examples of "Methane Reading" notations included in the memoranda:

> August 5, 1963 - Methane in 3U: 0.2% August 6, 1963 - Sequence of methane readings in 3U:

| Day shift   | 0.1%                    |
|-------------|-------------------------|
| Swing shift | Blast face at 5:30 p.m. |
| 6:00 p.m.   | 4.0%                    |
| 7:30 p.m.   | 2.0%                    |
| 10:30 p.m.  | 0.8%                    |
| 11:00 p.m.  | Nil                     |

During the period August 7 through August 26 gas in amounts ranging from 0.1 to 5.0 percent was found at various locations.

During the recovery work and investigation, tests made for combustible gases by a company official and State and Federal investigators, using permissible flame safety lamps and permissible methane detectors, showed combustible gases ranging from 0.2 percent along 2 south at No. 4 crosscut to an explosive mixture at the face. Combustible gas in the amount 0.2 to 1.5 percent was detected along 3U from its entrance to within about 600 feet of the face. Following the explosion, ventilation was eventually provided by increasing the compressed airflow into 3U and proving compressed airflow into 2 south. This was the only means by which these areas could be ventilated sufficiently to dilute and remove the combustible gases from the mine until such time as the fan ventilating system could be restored and improved (see Table 1, Composition of Mine Air Samples Taken At the Cane Creek Mine After Explosion on August 27, 1963, and Table 2, Representative Composition of Hydrocarbon Gases Reported as Total Hydrocarbons in Table 1).

Permissible flame safety lamps were carried by the shift leaders (walkers) of Harrison International, Incorporated after the ignition of July 31, 1963. Tests for combustible gases were made by personnel of Texas Gulf Sulphur Company during and after drilling blast holes. Prior to the July 31, 1963 ignition, a representative of the U. S. Geological Survey had recommended that drill holes 10 to 14 feet in depth be drilled ahead of the face to release gas from the strata or give indications that gas might be encountered, and this recommendation was followed. In addition, a diamond drill test hole 110 feet long had been drilled recently in the face of 3U drift. This test hole was 35 feet ahead of the face of 3U at the time of the explosion. It was stated that on occasions gas released during drilling was of sufficient pressure to blow water out of the hole and on one occasion the gas pressure was strong enough to eject the drill steel--throwing the drilling machine and driller 20 feet up the drift. At times gas was released from fractures in the strata during mining operations. Reportedly, a lighted permissible flame safety lamp was hung in each drift close to the face and was observed occasionally. Apparently, the casual observing of the hanging lamp was considered proper gas testing, and the necessary usual type of gas tests were not made with regularity. Also, a flame safety lamp was suspended in the shop, and the flame of this lamp was observed occasionally and considered a gas test. There were occasions when a flame safety lamp was passed from one crew to another as the shifts changed in the shop and thus was not properly cleaned and serviced.

A broken flame safety lamp found in the shop during the investigation was sent to the Bureau of Mines laboratories in Pittsburgh, Pennsylvania for examination. Part of the findings were: The wick had been turned down to a point where a flame could not be initiated or supported. There was no evidence of charring such as would be expected when the fuel was exhausted in burning. Fuel was available and seemed to be of normal quality as indicated by the appearance of a 1-inch flame when the wick was extended to permit lighting with a match. Flame could not be established with the ignitor. The flame was extinguished when the wick was turned down to the position as found. The conclusions reached on the tests were: From the generally dirty conditions of the lamp and rusty gauzes, the safety lamp maintenance program was poor or the lamp had been abandoned and left in the mine. The position of the wick, the lack of normal combustion deposit on the gauzes, and the amount of gauze rust suggest that this lamp was not in use or burning just prior to the explosion.

<u>Water and Dust</u>: The mine development areas were dry. Water under pressure was piped to the working faces, and reportedly, all drilling when not in salt was done wet.

<u>Transportation</u>: Hoisting of muck and water was accomplished by 4 sinking buckets that ranged in capacity from 71 to 117 cubic feet. Two double-drum hoists were used to hoist the sinking buckets. Each hoist was equipped with Lilly hoist control systems and overwind safety switches. Two sinking buckets, operated in counterbalance by each hoist, were equipped with crossheads which traveled in rope guides. The 1-1/8-inch diameter hoisting ropes were attached properly to the sinking buckets. Compressed-air operated shaft doors and dump doors were provided.

Transportation of muck and materials between the shaft station and working faces was accomplished with Diesel driven shuttle cars. Men were also transported in the shuttle cars. Each car was powered by a Diesel engine rated at 110 brake horsepower at 2,000 rpm and equipped with a 24-volt electrical battery system and starter. The Diesel shuttle cars bore Bureau of Mines Approval Plates 2414. These Approval Plates, as issued, signify that the Diesel equipment had been tested and approved by the Bureau of Mines for operation in nongassy, noncoal mines, as defined in Bureau of Mines Schedule 24; the ventilation requirement stamped on each Approval Plate was 17,100 cfm. The Diesel shuttle cars were not approved for safe use in a gassy mine, as such cars are capable of igniting gas from the electrical components or heating of the exhaust manifold.

Following the explosion, four of these Diesel shuttle cars, Nos. 1, 2, 3, and 5, were inspected as to condition of intake, exhaust, fuel, electrical and crankcase engine systems, and of overall unit condition. Diesel shuttle car No. 4 was inspected for damage to the crankcase only. All Diesel shuttle cars were empty of muck. Exhaust gas conditioners on all cars contained sufficient water for normal operation. Only Nos. 3, 4, and 5 shuttle cars were in the immediate explosion area.

The No. 1 shuttle car, Serial No. 341, was found at the junction of 2U and 3U drifts and appeared to have been parked here as all controls were in "off" positions. All engine systems of this car were normal and the car appeared to be undamaged.

The No. 2 shuttle car, Serial No. 842, was found parked in 3U drift just over the start of the 14 percent grade, approximately 60 feet inby the junction of 2U and 3U drifts. This car was used for transportation by survivors of the explosion before they barricaded themselves and left parked at this location. The car was not damaged and all engine systems were normal.

The No. 3 shuttle car, Serial No. 843, was found on the downslope, 25 feet inby the junction of No. 2 south right and No. 2 south left. The right rear corner of the car was jammed against the east rib, blocking movement down the drift. The directional gear lever was in "low reverse" position and the traveling gear and conveyor levers were in "zero" or neutral position. The emergency brake lever was in "off" position. The light switch, found in the "off" position by the Diesel engineers, was turned off after the explosion by rescue team members. From the position of the front wheels and various objects around the car, it seemed likely that the car drifted against the east rib after the explosion, and from the position of the traveling gear, it seems unlikely that this car was moving under power at the time of the explosion. The engine intake system, exhaust piping, and exhaust conditioner appeared normal and undamaged. The exhaust conditioner contained water although the "make-up" tank was dry. The fill cap of the "make-up" tank was missing and the fill cap cover plate hinge was ajar, a condition that probably existed prior to the explosion. The engine fuel system, crankcase, radiator, and transmission appeared to be in normal condition.

The No. 5 shuttle car, Serial No. 880, was located in No. 3 south, 120 feet west of the shaft, the front or operator's end facing the shaft. This shuttle car had been driven to this location and parked at the beginning of swing shift; overall damage to this shuttle car was extensive; it appeared that most of the damage was caused by the explosion.

The No. 4 Diesel shuttle car, Serial No. 844, was found at the north end of the shop area in No. 3 south. Since this car was in the shop for general overhauling and was not in operating condition, a general inspection of its condition was not made.

<u>Electricity and Compressed Air</u>: Three-phase, 60-cycle power was received at the main substation at 69,000 volts and was reduced to 12,470 volts for distribution to the secondary substations. A delta-wye connected transformer reduced the 12,470-volt power to 4,160 volts for delivery underground.

The primary underground power was received through the shaft to the No. 1 crosscut load center from where it was dispatched to the 2 south, bin area, and 3U load centers. Proper overload and ground fault protection were provided. Secondary power at 480 volts was supplied to the face equipment, fans, and the shop. Multiple conductors and three conductor type G cables were used for secondary power distribution. Power for lights in the shop and shaft area at 110 volts was provided by dry type transformers.

Extensive damage on the cables was not observed except in the shop and shaft area and in the primary feeder to No. 4 crosscut load center, which was dislodged from the back and was on the floor for about 350 feet in 2 south. The No. 1 crosscut load center equipment was completely destroyed.

The frame-grounding conductors of the secondary and primary system were interconnected through the load centers and were carried out to the surface plant grounding medium. Ground fault relays deenergized the equipment in case of ground faults and regular checks were made on the face equipment to ensure the proper operation of the ground fault relays.

Power for the shaft pumps on the 1330 level was received from the surface at 2,300 volts which was also the operating voltage of the pumping equipment on that level; it was reduced on the 1330 level to 440 volts and transmitted to the 1760 and 2200 level pumping equipment. The 1760 and 2200 level pumping equipment was not in use. Power at 110 volts for the shaft signal system was also supplied from the surface to junction boxes on each level to which 4 signal bell knockers were connected.

The electric face equipment in the 3U section was of the permissible type and consisted of one 15RU Joy mining machine, one CD-43 Joy drill, and one 967-LC Goodman loader. In addition, two National Mine Service 60-ED Diesel shuttle cars were provided. Fire-resistant trailing cables, (Type G), were used on the loader, cutter, and drill and were provided with suitable overload protection through circuit breakers installed in face distribution

10

boxes. Examination of this equipment showed one bolt missing from the starter compartment and two bolts missing from the main breaker compartment of the drill; and an opening in excess of .004 inch in the left headlight between the headlight cover and lens of the loader. The two shuttle cars were examined; however, there was no indication of electrical arcing or burning. Similar face equipment was used in 2 south. Examination disclosed one bolt broken and an opening in excess of .004 inch in the main breaker cover of the cutter; three missing bolts, one broken bolt, one loose bolt and an opening in excess of .004 in the controller cover and openings in excess of .004 in the controller cover and lens on both headlights of the drill; and two bolts broken, two bolts missing and one bolt loose on the starter compartment of the loader.

Permissible type 15-horsepower fans were used to ventilate the load center installations and shop. Nonpermissible type 25- and 40-horsepower booster fans were installed in the vent tubing. Nonapproved type magnetic starters and push buttons were used on the nonpermissible type fans. Permissibility defects were not observed on any of the permissible type fans.

In the underground shop area a permissible type loader and two shuttle cars were being repaired at the time of the explosion. Examination showed that three bolts were broken, one bolt was missing, and there was an opening in excess of .004 inch in the starter compartment of the loader. The No. 4 shuttle car was under major repairs. It was observed that the ground cable for the electric welder was equipped with a piece of reenforcing steel instead of a standard ground clamp.

The forces of the explosion had sheared the bolts in the metal shield that protected the 24-volt batteries of No. 5 shuttle car and it was torn loose. The batteries were electrically connected; however, the top battery was destroyed.

An electric hand-held drill, grinder, several shop tools, including a 50-foot section of oxygen and acetylene hose taken out of service, and parts of the shop panel and battery charger were scattered throughout the shop area.

The shop area had been illuminated with 8 incandescent light bulbs in weatherproof sockets and two outlets had been provided for connecting power tools and extension cords.

During the inspection of the distribution system and equipment, it was noted that the distribution equipment was well installed and that the face equipment, except for the few defects mentioned, was generally well maintained. Compressed-air for operating stopers, jackleg drills, sump pumps, and air driven fans was provided by compressors located on the surface. These included an Ingersoll-Rand 750 cfm, an Ingersoll-Rand 1,000 cfm, and a Babcock-Wilcox 2,700 cfm. A mobile 600 cfm compressor was used as standby. The compressed air was taken down the shaft through a 6-inch pipe line, and 3-inch pipe lines extended to the face areas in 3U and 2 south.

Oxygen-Acetylene Cylinders and Cutting Torch: Acetylene and oxygen cylinders were found in the shop with gages still attached but damaged. The hoses leading to the cutting torch were torn away at the gages and found at the outby end of the No. 4 shuttle car stretched out under debris. The values of the cutting torch were found open  $2\frac{1}{2}$  quarter turns. The value wheel on the acetylene cylinder had been blown off, but the valve on the oxygen cylinder was intact. Later when tested on the surface, the acetylene cylinder was empty and the oxygen cylinder contained 1,100 pounds pressure. A small acetylene cylinder with the valve closed and two oxy-acetylene torch ignitors were also found in the area along with other scattered tools. Short sections were cut off the ends of the acetylene and oxygen hoses where they were broken off the gages and these with the damaged acetylene and oxygen gages were sent to the Bureau of Mines laboratories in Pittsburgh for examination. The broken ends of the hoses made reasonable fits with the portion of hoses in the ferrules on the gages. The reports on the tests were summarized thusly: None of the exhibits showed evidence of damage from internal disruptive forces or from overheating by local persistant flame.

Samples of residue scraped from the outside of the oxygen and acetylene cylinders and samples of fine solid material collected in the shop area were sent to the Pittsburgh, Pennsylvania laboratories for tests. The summary of the tests was as follows: Examinations of thirteen samples of materials, brushed or scraped from various locations and equipment in the underground shop area, and two from a flame safety lamp recovered from the mine, were made by chemical, X-ray diffraction, emission spectrographic, infrared absorption, and microscopic methods.

1. The samples principally were a mineral mixture of halite, silicon dioxide (alpha quartz), calcium carbonate, dolomite, and calcium sulphate. Small amounts of magnetic metallic particles and wood splinters were present.

2. All samples contained oil; in amounts ranging from approximately 1 to 21 weight percent.

3. The oil, acetone-extracted and filtered from the solid material, was dark brown-black in color, very viscous, and resembled heavy, oxidized lubricating oil.

4. No evidence was obtained that adsorbed acetylene was contained in two samples of deposits from the acetylene cylinders or in two other samples tested.

5. No evidence was obtained that soot or low density carbon particles were present in the acetone-insoluble residues from any of the samples.

Another oxygen cylinder and another acetylene cylinder were found on the shaft station on the west side of the shaft. The gages were blown off and the valves on each cylinder were found in the shut-off position. The hoses leading to the torch were strung out toward the shaft.

These tests indicate that the combustible gas involved in this explosion was not acetylene.

<u>Illumination and Smoking</u>: The shaft station and shop were illuminated by 110-volt incandescent light bulbs in weather proof sockets. Each underground workman carried a permissible electric cap lamp. Mobile equipment was equipped with headlights.

Prior to July 31, 1963, smoking was practiced freely in the mine; the flame from a cigarette lighter set off the ignition which occurred on this date. Following the ignition, the Industrial Commission of Utah required that smoking in the mine be prohibited and that "No Smoking" signs be posted. Although the "No Smoking" signs were posted, employees were not searched to see that smoking materials were not carried into the mine, and it was quite evident that smoking underground was continued by some persons. Numerous cigarette butts, empty cigarette packages, a book of matches, and other empty match books were found during the investigation in areas driven after the July 31 ignition.

<u>Mine Rescue</u>: The Texas Gulf Sulphur Company maintains a mine rescue station at the mine. Before the explosion, the equipment included 6 McCaa self-contained 2-hour breathing apparatus and spare parts, an electrically driven oxygen pump, 6 Chemox self-generating oxygen breathing apparatus, one permissible mine rescue communication system, a 1,000 foot life line, 6 permissible flame safety lamps, 48 self-rescuers, and 10 first-aid kits. Following the explosion, 10 Universal gas masks and 6 additional permissible flame safety lamps were purchased and used in the rescue and recovery operations. Employees had not been trained as a rescue team.

#### INTRODUCTION

This is an investigation report of a mine explosion disaster that occurred June 8, 1979, at the Belle Isle Mine, Cargill, Inc., near Franklin, St. Mary Parish, Louisiana, MSHA mine I.D. Number 16-00246. The investigation is made pursuant to the provisions of the Federal Mine Safety and Health Act of 1977, Public Law 91-173, as amended by Public Law 95-164 (30 USC 801 <u>et</u>. <u>seq</u>.).

The investigation was authorized by Thomas J. Shepich, Administrator, Metal and Nonmetal Mine Safety and Health, Mine Safety and Health Administration. The purposes of this investigation were: to determine the location and cause of the explosion, including conditions and practices at the Belle Isle Mine that resulted in the explosion; to make recommendations to prevent a similar occurrence; and, to examine the MSHA's related policies and practices. Briefly, for the reasons set forth in this report, the investigators believe that the underground explosion was initiated in 8 Main Entry East near Room 10 where an explosive mixture of flammable gas was ignited by burning electrical conductor insulation, or arcing electrical wires, or both.

i

#### SUMMARY

On Friday, June 8, 1979, an outburst of flammable gases and salt occurred following a face blast in 8 Main Entry East at about 2300 hours, and a gas explosion occurred in the mine approximately 10 minutes later. At the time of the explosion, 22 persons were in the mine. Ten persons were on the upper level and twelve persons were on the lower level. Seventeen persons were rescued and five persons died as a result of the explosion.

A few minutes before 2300 hours, near the end of the shift, all employees left their working places with the exception of two men who were designated to initiate blasts in three working places charged with explosives. Twelve of the employees attended a scheduled meeting and eight employees were enroute to the No. 1 Shaft to be hoisted to the surface. The blasts were initiated from 7 Main Entry East at Room 13 by the two designated employees, and approximately 10 minutes later the explosion occurred. According to the autopsy reports, four of the fatalities occurred as a result of acute pulmonary hemorrhage secondary to alveolar rupture due to the air blast in the mine explosion. The fifth victim apparently died from a combination of acute pulmonary d hemorrhage and carbon monoxide poisoning (See Appendixes C and D). The autopsy report on the fifth victim showed a carboxhemoglobin saturation of 75 percent. Three victims were found within 300 feet of the No. 1 Shaft Station. The fourth and fifth victims were found about 1,400 feet and 1,800 feet, respectively, from the No. 1 Shaft Station. All victims were recovered by mine rescue teams within 41 hours after the explosion. The rescue effort involved 73 dedicated mine rescue team members who assembled from local mines and from around the Nation and involved a total of 14 team entries into the mine in that period of time.

From a position of hindsight, there were a number of significant events which in combination should have established the forewarning of the potential disaster. However, when the events were considered one at a time, on a mine-by-mine basis, the overall significance was overlooked or lost. The multiple indicators of significant gas problems explained hereinafter in this report in the Belle Isle Mine were not adequately correlated by either MSHA or Cargill management.

## MSHA'S INITIAL RESPONSE

Charles von Dreusche, Mine Manager, notified Wayne D. Kanack, District Manager, South Central District, Mine Safety and Health Administration (MSHA), Dallas, Texas, at 0030 hours on June 9, 197

### EVENTS BEFORE AND AFTER THE EXPLOSION

During the day shift of June 7, 1979, the face in Room 14 south of 7X Entry East was drilled in preparation for blasting. During the investigation MSHA investigators were informed by Cargill employees that methane had been released from these blastholes. The face was charged and blasted at the end of the evening shift. A methanometer was not available underground for use by the evening shift.

ŝ,

:

Ţ.

÷

Two miners were assigned to pick up blasting lines in Room 14 at the beginning of the day shift on June 8. Upon arriving at Room 14, they heard an audible gas emission and observed characteristic cone-shaped blown-out pockets in the right side and upper left-hand corner of the face. The audible emission was coming from the center of the left blown-out pocket and was described as sounding like air coming out of an inner tube. The sound could be heard above the noise created by a nearby ventilation fan. A short time later, John McFarlain, the individual assigned to monitor gas emissions, arrived and obtained methane readings sufficiently high to warrant withdrawal of employees. The heading was placed off limits, smoking and open flame restrictions were established, and ventilation adjustments were made in an attempt to dilute the methane in the face.

The face of 8 Main Entry East to the east of Room 13 was drilled. The drilling was toward the projected intersection of 8 Main Entry East and Room 14, where the gas was emitting. Approximately 48 feet of salt separated the two advancing faces.

Shortly before the end of the day shift an electrical fire occurred in an auxiliary fan motor and cable located south of the shop area in 2 Main Entry South. A mine evacuation was underway when it was determined that the fire was minor and brought under control. Employees in the vicinity of the fire had evacuated to the No. 2 Shaft station. Some employees assigned to remote sections of the mine failed to receive notifications and remained in their work areas.

Elray Granger, General Mine Foreman, and A. J. Boutte, Shift Foreman, assigned to the evening shift, met with day shift management at approximately 1530 hours on June 8, 1979. This meeting concerned normal production activities and it was reported by the participants that there was no mention of the methane gas emissions, as noted above, in the east area. Despite the presence of flammable gases in this area, mine personnel did not monitor for concentrations of these gases. Methane detection equipment was not available in the mine during the evening shift. Normally, shift personnel did not sample for methane or other flammable gases during the evening shifts, but relied solely on sampling done during the day. Employees of the evening shift were assigned their regular duties of hauling salt from lower level production areas to the crusher, drilling, undercutting and charging blastholes in the faces and floors in the upper level East area. Sometime after lunch, diesel emission accumulations from the haulage equipment caused the production crew to leave the lower level and begin hauling salt from headings on the The crew hauled salt from Room 14 south off upper level. 7X Entry East where the gas emission had occurred during the day shift. Another crew drilled floors in Room 14 south of 6 Main Entry East and Room 11 north of 8 Main Entry East, and undercut the face in 8 Main Entry East at Room 13. After the drilling and undercutting was completed, the three rounds were charged by the undercutter and drill operators with assistance from haulage personnel and Shift Foreman Boutte.

At approximately 2250 hours, eleven employees assembled at the bottom of the lower level manlift, off 1 Main Tunnel South, for a scheduled meeting. Two additional employees, Adam Sampay and Amedee Olivier (victims), returned to detonate the three charged rounds from the blasting board at 7 Main Entry East, Room 13. Eight other employees, including victims Zimmerman, Collins and Mayon, were on the upper level preparing to leave their work areas at the end of the shift.

As A. J. Boutte stepped out of the underground operations office on his way to conduct the meeting, he heard one of the scheduled blasts and assumed it was the floor round in Room 14 off 6 Main Entry East. A. J. Boutte proceeded to the manlift area and conducted the meeting for approximately seven minutes. Just as he finished the meeting about 2308 hours, a larger explosion was heard followed almost immediately by extreme concussion and strong winds, which rapidly rose to destructive levels. The explosion forces and winds destroyed or damaged equipment and fixtures throughout the mine and caused injuries to some of the 11 miners at the meeting. At the time of the explosion, A. J. Boutte was kneeling on the front seat of his production truck with his back to the steering wheel talking to the men. Ten employees were seated on benches in the bed of the production truck. Alton Oppenheimer was standing along-side the passenger side of the production truck, which was a 3/4-ton open cab military-type Jeep. Some of the men were knocked down by the forces of the explosion.

It was extremely dusty and visibility was zero due to the hurricanelike winds. A. J. Boutte became separated from the 11 employees. A. J. Boutte took the escape route south on 1 Main Tunnel South and through the first set of corrugated culverts to the Airway Tunnel, which led to the No. 2 Shaft. At the Airway Tunnel, A. J. Boutte was blown approximately 30 feet down the tunnel toward the No. 2 Shaft by an increase in wind velocity. Due to the extreme heat and high wind in the Airway Tunnel, A. J. Boutte decided to crawl back to the corrugated culverts and cross over 2 Main Tunnel South. At this time visibility was zero in 2 Main Tunnel South, but the wind was not blowing as hard as in the Airway Tunnel and the extreme heat was not present. A. J. Boutte was disoriented and confused while going up the equipment ramp. He fell down, stumbled, weaved from side to side and bumped into various objects in the travelway. A. J. Boutte was confused and thought he was lost until he heard Peggy Blaney screaming. As he walked toward the screaming sounds and made contact with Peter Boutte and Perry Thompson, who were enroute to the No. 2 Shaft. A. J. Boutte advised them about the extreme wind and heat in the Airway Tunnel to the No. 2 Shaft and stated that the intake air appeared to be coming down the No. 1 Shaft at this time, rather than the No. 2 Shaft. The three men started toward the No. 1 Shaft. A. J. Boutte found Peggy Blaney, who kept screaming that she was burning and on fire. Blaney was dragged part way and eventually crawled the rest of the way to the No. 1 Shaft.

21.75

34 2137

Floyd Linton had followed A. J. Boutte to the corrugated culvert but then returned to the other ten employees at the manlift. Linton, who was trained in mine rescue, suggested that all the miners join hands and try to make their way through the escape route to the No. 2 Shaft (See Appendix O). Hurricane-like wind made the travelway extremely dusty and visibility was zero. The miners had trouble breathing and the dust caused them to choke and cough. The temperature increased considerably. The ll miners moved slowly south through 1 Main Tunnel South to the corrugated culverts and proceeded north in the Airway Tunnel toward the No. 2 Shaft. The miners were subjected to intense heat but there was no evidence of fire in the Airway Tunnel. The air movement at the No. 2 Shaft appeared to have reversed from intake to exhaust because the main fan which was located underground was destroyed by the explosion. The miners again had trouble breathing. All of the miners were carrying self-rescuers but no one used them.

Floyd Linton climbed on top of a salt stopping by the fan located in the Airway Tunnel and advised the others that the air was better at that location. The other miners climbed up and joined him. A cloud of smoke came toward them and they decided to move toward the No. 2 Shaft. The 11 miners arrived at the No. 2 Shaft at approximately midnight. Several of the men sat on boxes of explosives which were stacked on pallets approximately 50 feet

39

and w

from the No. 2 Shaft. There were an estimated 350 fifty-pound boxes of explosives at this location. One of the miners began hitting the No. 2 Shaft station gate with a short piece of pipe in an attempt to let the people on the surface know that they were alive. The mine phones and the cords used to signal between the mine level and the surface were blown out. Audio and visual communications eventually were made with the surface by shouting and use of cap lamps.

Immediately after the outburst, shot-firers Sampay and Olivier (victims) abandoned their vehicle near the blasting board at 7 Main Entry East Room 13, and moved on foot toward the shaft. Sampay was found approximately 3,300 feet from the vehicle in 2 Main Entry West at Section 1. Olivier had traveled about 2,600 feet and was found in 1 Main Entry South, adjacent to Section 4 (See Appendix P).

Five of the remaining eight employees on the upper level were enroute to the No. 1 Shaft to be hoisted to the surface at the end of the shift. Herman Zimmerman (victim) was riding in a jeep-type vehicle in 1 Main Entry South when the explosion forces knocked the vehicle out of control. The vehicle came to rest with the rear half hanging over the edge of the P-39 conveyor decline and Zimmerman fell about 30 feet to the floor of the decline on the east side of the conveyor. Jason Mayon, the driver, remained behind the wheel during the explosion but as he got out of the vehicle he also fell onto the conveyor and received back injuries.

Perry Thompson and Peter Boutte were riding on a small tractorlike "boss buggy" some distance behind Zimmerman and Mayon, and although one of them was blown off the vehicle, neither man received a significant injury. These two men made voice contact with Jason Mayon and the three men walked the short distance to the No. 1 Shaft Station. Eldridge Roman, the tunnel conveyor operator, who was working alone in the 1 Main Tunnel South area, also arrived at the No. 1 Shaft slightly injured.

1

The telephone by No. 1 Shaft Station was broken, so Mayon and Roman went to the tunnel to use the telephone, but it was also out of order. Parts from this phone were used to repair the phone at the No. 1 Shaft Station. A. J. Boutte then phoned Elray Granger who was on the surface and related the location of the six employees at the No. 1 Shaft Station.

Prior to the explosion, three employees were sitting in a vehicle adjacent to the No. 1 Shaft Station while waiting for the end of the shift. This vehicle was blown from the shaft area into 2 Main Entry South. Donald Mayon and Richard Collins died from the explosion forces and Peggy Blaney was injured seriously. General Mine Foreman Elray Granger had been underground throughout the shift but had returned to the surface around 2300 hours via the No. 1 Shaft. Granger proceeded to the mine office which was adjacent to the No. 1 Shaft collar. About 10 minutes later, Granger heard the underground explosion and ran outside the mine office. He stated that the sound of the explosion first started faintly and then grew louder and louder until it reached a peak and held for several minutes. Granger stated that the sound was like five freight trains and was coming out of both the No. 1 and No. 2 Shafts along with dust, smoke and debris. Granger ran back into the mine office and phoned Charles von Dreusche, Mine Manager, at home to report the explosion. Granger then went to the No. 1 Shaft collar with Terry Hebert, Topside Foreman, where they found the mancage a few feet above the collar and a great deal of debris and loose power cables around the collar area.

Granger and Hebert decided to clean up the area and to send the cage down to the mine level with a communications radio aboard. While they were doing this, the mine phone at the headframe rang. Granger answered and talked to A. J. Boutte who was at the upper level shaft station with five other people. Boutte reported that Zimmerman, Donald Mayon and Collins were dead and that he thought the rest of the employees also were dead. A. J. Boutte called again asking the surface to hurry because he could see "the bad air coming". About five minutes later, or approximately 2340 hours, the No. 1 Shaft collar was cleared. The cage was lowered, and the upper level survivors -- A. J. Boutte, Eldridge Roman, Peter Boutte, Perry Thompson, Jason Mayon and Peggy Blaney -- were hoisted to the surface. The empty cage was then returned to the mine level with a radio on board in case other survivors reached the Shaft Station.

÷

At the time of the explosion, the No. 2 Shaft conveyance also was at the collar. The explosion forces lifted the cage to the top of the headframe where the safety dogs engaged because of the slack rope. The cage was lodged in the upper part of the headframe. Clyde McKay, No. 2 Shaft Hoistman, heard pounding signals and other noises from the bottom of the No. 2 Shaft at approximately 0045 hours, June 9, 1979. Efforts were then concentrated on clearing the No. 2 Shaft conveyance to effect the rescue of the miners at the lower level Shaft Station.

The cage was lowered, but it became "hung up" at 500 feet and also at 700 feet below the shaft collar on steel plumb lines left from the shaft-sinking operations which were entangled with all four guide ropes (See Appendix NN). The cage was raised and dropped several times until the obstruction was cleared, and then the cage was lowered to the 11 men -- Al Thompson Alton Oppenheimer, Floyd Linton, Charles Verdun, Joseph W. Boutte, Girault Frilot, Joseph Buttler, Brian McFarlain, Prentis Shaw, Esau Mitchell and Lenneth Hill -- who were at the lower level Shaft Station.

These miners reached the surface at approximately 0245 hours on June 9, 1979. All 17 survivors were transported by helicopter to the Franklin Foundation Hospital in Franklin, Louisiana. At the time, five miners were still underground, one had been determined to be a fatality and the location of two other miners was known and it was believed that they were fatalities. The location and condition of the remaining two miners were not known.

View of rope damaged when cage was blown to the top of No. 2 shaft headframe.

Plumb line and signal wire pulled up from No. 2 Shaft sump. Rope around the cage in the headframe and around the cage guide rope delayed recovery of survivors.

# APPENDIX NN

Viewing east or inby side of the Gradall scaler along south rib at 8 Main Entry East at Room 11. Paint does not show heat deterioration.

Viewing the west or outby side of the Gradall. Paint shows heat deterioration and a heavy salt encrustation from a high, hot wind moving east is evident.

Heat damage in cab of the Terex loader at 7X Entry East and Room 10 lower level. Vinyl seat covering burned off, leaving edge - scorched foam.

Rear recapped tires showing chars and salt on Terex loader at 7X Entry East and Room 10 lower level.

Viewing west from 2 Main Entry South just west of No. 1 shaft station. Overturned cart at the right was one in which two victims and one survivor were riding.

Viewing north to south from the P-39 belt line decline in 1 Main Entry South survivor and victim were riding in the Jeep shown overhanging the decline cut.

Main fan in airway tunnel south of No. 2 shaft. Portion of the metal fan bulkhead found in No. 2 shaft sump.

Remnants of free-standing fan originally in No. 2 Main Entry South, south of 7 Main Entry East, blown north to between 4 and 5 Main Entry East in 2 Main Entry South.

1975 blowout in 7 Main Entry West Room 4.

Viewing south from 7X Entry East at outburst salt piled in Room 13.

Transformer blown west from 1X crosscut east of 2 Main Entry South into middle of 2 Main Entry South.

Viewing north at damaged maintenance office and parts room in 2 Main Entry South, north of 1X crosscut.

Truck at 2 Main Tunnel West of 1 Main Tunnel South in which the 11 men were sitting and one standing for the safety meeting.

Pictures at the same location as above. Manlift escapeway in background with wood debris from cabinets.

Top of manlift at 2 Main Entry East just west of 1 Main Entry South. Entire frame moved to the west 2 feet.

Terex truck in 1 Main Entry South moved north by the explosion into the reclaim bin located just north of 2 Main Entry East.

Pictures show the decay of the explosion forces as they moved north in 1 Main Tunnel South. Conveyor system in 1 Main Tunnel South. Upper picture shows complete destruction of the conveyor just north of the primary crusher between 5X crosscut and 5 Main Entry East. The middle picture shows partially damaged conveyor north of 5 Main East and the lower picture shows the conveyor just south of 3 Main Entry East.

Turned over red shop truck. Picture taken viewing the truck from the south. Truck was located in 7 Main East Entry just west of Room 13.

Turned over core drill in the southeast corner of Room 2 cutout just south of 9 Main Entry East.

Negative terminal on overturned maintenance shop truck in 7 Main Entry East and west of Room 13. The terminal exhibited that lead had melted.

Pinched positive conductor on overturned truck. Bare copper wire exposed.

Viewing to the southwest at the face drill located at the southeast corner of 7X Entry East and Room 13. Drill was blown 50 feet to the southeast.

Viewing southeast at the bottom side of the face drill above.

Explosives loading Jumbo facing south. Located just north of 8 Main Entry East along the east rib at Room 12.

Portable blasting board impaled on south side of engine of loading Jumbo. Board was located between Rooms 11 and 12 in 8 Main Entry East before the blast and distributed power to the 8 Main East face shot and bench shot at Room 11X. ないです

FORE THE Gil Conservation Commission MANTA FE. NEW MEXICO April 20, 1955 IN THE MATTER OF: CASE NO. 862 - Regular Hearing TRANSCRIPT OF PROCEEDINGS ADA DEARNLEY AND ASSOCIATES COURT REPORTERS ROOMS 105, 106, 107 EL CORTEZ BUILDING TELEPHONE 7-9546 ALBUQUERQUE, NEW MEXICO

ないた。例での言語

BEFORE THE OILCOONSERVATION COMMISSION Santa Fe, New Mexico April 20, 1955 IN THE MATTER OF: Application of the Commission upon its own motion for an order (a) creating the North Benson-Queen Oil Pool in Eddy County, New Mexico, described as follows: Township 18 South, Range 30 East E/2 Section 33; W/2 Section 34 Case No. 862 and (b) prescribing rules and regulations pertaining to the proposed pool in accordance with provisions of Order H-111, which pertains to the drilling and completion of oil or gas wells within the designated "potash - oil" area. EEFO.LE: Fr. S. S. (Johnny) Walker Mr. William B. Macey TRANSCRIPT OF HEARING MR. MACCY: The next case on the docket is Case 862. S. J. STARLEY, called as a witness, having been first duly sworn, testified as follows: DIRECT EXAMINATION iy Ha. KITTS: a fill you state your name and position, please? A S. J. Stanley. Engineer for the Cil Conservation Commission. 2 dr. Stanley, since the last meeting of this case when it was first heard, you have been appointed to a Committee to study further this matter? ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE. NEW MEXICO TELEPHONE 3-6691

A Yes, sir, we have had two meetings in Carlsbad to study this particular problem.

Q Mr. Stanley, in connection with your study, you prepared an exhibit which you wish to comment upon at this time, and introduce?

A Yes, sir, I have prepared one exhibit and also have obtained two exhibits from the United States Geological Survey, which I intend to introduce into the record.

Q This plat on the wall is your Exhibit 1?

A Yes.

That was prepared by you?

A Yes, sir, under my direction.

Q Will you proceed with Exhibit 1 and explain what that shows

A Case 862 deals particularly with Order H-111. The objective of Order H-111, generally referred to as the Potash Order, is as follows: "The objective of these rules and regulations is to prevent waste, protect correlative rights, assure maximum conservation of oil and gas resources of New Mexico and permit the simultaneous economic recovery of potash minerals in the area hereinafter defined."

The potash - oil areas are divided into two parts. Area A includes the various parts in which potash mining operations are in progress, and Area E includes the various parts of which potash mining operations are in progress or in which corine tests indicate potential potash reserves.

Therefore, Exhibit No. 1, marked in red coloration includes the entire area defined in Order H-III of potential potash recovery determined by actual exploration or core test date. The scale of the map showing the potash area is one inch equal to two miles, and therefore it can readily be seen that the area so defined is very large in extent, and for the sake of understanding the area itself I would like to point out on Exhibit No. 1 various Landmarks. Here is Artesia, New Mexico, here is Carlsbad, New Mexico and here is Hobbs. New Mexico.

Q That shows both area A and B?

A Yes, sir, it incorporates both areas.

In Order E-111 in the problem before the Commission, the rules specifies the casing program of wells drilled to a shallow depth of less than 5,000 feet, and deeper wells drilled to depths of greater than 5,000 feet.

The surface pipe in shallow holes will be landed in the red bed section, and cemented to the surface. The salt string will be set between 100 and 200 feet below the base of the salt and cemented to the surface. The oil string shall be cemented with sufficient cement to protect the oil pay zone. Now, in lieu of offsetting a salt string, an operator can pull such string whenever it is landed for water shut-off and then the oil string shall be cemented to

I, at this particular time, would like to read into the record  $\frac{43}{45}$  the problem before  $\frac{43}{45}$  pertaining to two wells of Sizms and Reese Oil Company, which have been completed within the designated potash area as defined by Order R-111. The Simms and Reese Oil Company's Mc Clay No. 1, located 1980 from the south and 660 from the east of Section 33, Township 18 South, Range 30 East, perforations are

2,844, that is the top of the perforation. The seven inch casing is set at 763 feet, four and a half inch casing at 2,093 feet

cemented with 100 sacks. The top of the anhydrite, by our informa-

ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691

tion is 250 feet. The top of the salt is 550 feet, the base of the salt is 1,494 feet and the top of the Queen is 2,810 feet.

The Simms and Reese Oil Company's McClay No. 2, 1980 from the north and 660 from the east of Section 33, Township 18 South, Range 30 East, perforations, 3,036 to 61 feet. That is 3,036 to 3,061 feet. Eight and five inch casing set at 590 feet with 80 sacks. Five and a half inch casing set at 3,064 feet with 30 sacks. The top of the salt in this well is at 560 feet, the base of the salt is at 1,495 feet, and the top of the Yates at 2,626, and the top of the Queen to the producing fromation is 2,844 feet.

Q I would like to interrupt for a moment here. You are aware the original applicant in this case, Simms and Reese Oil Company, stated in their application and testified at the last hearing, that they did not believe that in the area concerned, the area of their wells, there was potash salt in commercial quantities. Do you have any information as to that? Bid your study go that far?

A I don't know whether there is potash of commercial quantities in that area or not.

ų Isee.

A In fact, in reading the Simms and Reese Gil Company, the McClay No. 2 file, I might add this is a Federal well. That on the Federal form of sundry notices and reports on wells, the operator, Simms and Reese Gil Company makes the following statement.

"We will drill to approximately 3,000 feet and set eight and five inch surface casing and cement back to surface. Five and a half inch casing will be set and cemented through the red sand and sand fracted. We will comply with New Mexico Oil Conservation

> ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691

Commission's Order R-111 on any modification thereto."

Q That was filed well before their application for exception to R-11, wasn't it?

A Yes, sir. The point that Simms and Reese Oil Company have argued is that potash is not present in this area. It is evidently unecomomical to produce oil from this area in stripper production with the cost of cementing, without exception of Order R-111. The date of the Order R-111 is July 10, 1951, and since that time 18 wells have been drilled in the potash area. Of the 18 wells that have been drilled, 16 wells have complied with the order and the two wells of Simms and Reese Oil Company seek an exception to this rule in this area where the wells are drilled.

To better acquaint ourselves with the problem of the potash company and the oil companies, two meetings were held in Carlsbad prior to this hearing. Certain topics were discussed and probably should be mentioned and introduced into the record. Area A as defined by this order, is a continuously changing picture. I have what is marked Exhibits No. 2 and 3, showing the irregular pattern of potash occurrences.

4 Were those prepared by you, Fr. Stanley?

A No, sir, these were prepared by the United States Geological Survey, and they show A scale on the exhibit. However, that is considered a trade secret and, therefore, it is not actually defined in any one particular area referred to as actual description referred to as township, range.

Q Are you satisfied with the accuracy of these?

A No, sir, I know nothing about the exhibits. All I want to

What I would like to show with these two exhibits is the irregular occurrence of the potash area as determined by core drill. The closer spacing of core well holes could even connect the areas shown in Exhibits 2 and 3, and probably actual mining operations could change the entire picture.

Today the potash industry is able to mine, and bodies of the thickness of 18 inches, as we understand, it is possible to mine sylvite, an ore of potash, or sylvanite with a 14 percent content, or inductive with eight percent. In some instances the percentage of ore can be lower. In other words, with ever changing and improving techniques in mining, as is true in the oil business, and especially refining continually changes the commercial extent of the boundaries of the proven potash reserves.

It has been stated by the potash companies that porosity exists in the salt section that is mined. It has been definitely proven in the oil business that the salt section is charged in the Monument and Hobbs Pool and charged with gas. The charging of oil and gas in these pools was probably man made by casing leaks.

The point I am trying to make is that I feel that porosity and permeability exists in the salt section throughout Lea County, that the extent of charging the zone, and that is the salt zone, from one well would depend on the amount of gas present, and, of course, the pressure of that particular gas. Fortunately the wells of Simus and Reese Oil Company, if typical of the area, have low gasoil ratios and also have very low bottom hole pressures. The potash areas defined is unexplored for all practical purposes, for oil accumulation and, therefore, who can say that high pressure wells with considerable gas volumes will not be obtained at shallow depths.

> ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691

One interesting point that was mentioned at these meetings was a method of mining ore. This type of mining refers to the removal of pillars, after the conventional mining is completed, these pillars a supports are in an order of 100 foot in diameter. One pillar after another is removed until the earth above it subsides. This subsidence is evident at the surface of the ground. It is also believed that horisontal slippage occurs during the period of subsidence, this would have the tendency to shear off the casing of eil well; regardless of the number of strings of casing run in medern completion practices. The well would never be plugged properly since it could never be reentered. This subsidence would effect both the deep and shallow wells. I can see where possible charging of the mine workings would result.

It has been stated that the recoverable potash, based on potash mines at the present going price, is 154,000.00 per acre. 90 percent of the domestic potash, or I might say that the domestic potash? in excess of 90 percent is mined in this area defined by Order K-111.

In conclusion, I wish to state that I have no recommendations in the case, that the Commission will have to recommend.

When Stanley, let me ask you this. You stated that you had no knowledge as to whether in the area in question there was potash salt in commercial quantities or not, is that correct?

A That is right.

G Assuming that there is potash salt in conservial quantities in that area, would you care to make any comment on the casing program set out in R-111, and the casing program of the Simms-Reese Company, as it would protect any such salt? Do you have any comment

on that?

A Could I elaborate on my answer?

Q Certainly.

A I have studied all the wells in the Hebbs Pool from a corrosion standpoint, have inspected every well in that particular pool, and have also inspected all the wells or virtually all the wells in the north half, or half the wells in the Monument Pool. The casing program as defined in Order R-111 is not exactly the casing program that I would recommend in the potash area, provided that there was no horizontal slippage. However, I do not recommend that the casing program be altered as defined in R-111. My theories on casing program in this particular area and from the experience that I have had in observing the corrosion problems in Hobbs and the Honument Pool is as follows: If I intended to write an order to protect any potash area or any mine workings, I would write an order whereby the surface pipe would have to be set at 100 feet or 200 feet below the salt string in this manner.

MR. MACEY: Below the salt string?

A Yes. Not set any surface pipe below the salt section, not set any surface pipe at all, but set it — Assume that this is the salt section, set it a hundred feet below and cement that particular pipe to surface, then the oil string should be cemented in such a fashion that the cement behind the pipe shall come to a point below the oil section, or below the salt section, excuse me. Therefore, at any time we observe this in the Hobbs and Monument Pool, the potash companies, the oil companies or any individual could go to that particular well in question and observe between the annulus at the surface pipe and oil string whether a leakage occurred at any

> ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691

particular time during the life of the well.

At the present time, by cementing through the salt section, and we have found this in Hobbs and in Monument, there is no method at the surface of determining whether you have a leak or not. The only method that could determine whether you had a leak or not in any particular well, whereby the oil string is comented through the salt section, it to run your tubing with a packer in such a fashion that you could observe or record the pressures between the tubing and the oil string.

However, I am not making any recommendations that the casing program be altered in Order R-111.

Q Do you feel that the casing program set forth in R-111, you feel that if that were followed it does afford protection to the potash salt section?

A I think it affords protection by merely running an oil string through the salt section.

Q You feel that the cementing helps appreciably?

A I think it possibly could help, but there would be no known method of ever testing the well, due to the fact that most of the corrosion is due to hydrogen sulphide, as we have observed in the Hobbs Pool, that the corrosion is internal, that it is not external, adjarent to the salt section. That pipe pulled in the Hobbs Pool and in the Monument Pool, adjacent to the salt section showed that it would be in condition A, that is considered in new condition externally, but that the holes were formed from the inside by hydrogen sulphide. I do not feel that a rim of cement around this pipe a fraction of an inch in diameter in some cases would protect

> ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691

that particular salt or potash section, and it would aggravate the problem if you had considerable bottom hole pressure, or gas pressure. I feel that cement would not be able to hold, say, a thousand pounds pressure as we have in the Hobbs Pool, or the Monument Pool.

MR. KITTS: That is all.

MR. MACEY: Any questions of the witness? Mr. Rhodes?

# CROSS SXAMINATION

By MR. RHODES:

Q These discussions with the potash operators, was any mention made of the possibility of bringing water in on the potash by drilling in the area?

A You mean from the surface or from the bottom?

Q Below the line water table.

A They do seek protection by setting the surface pipe to prevent any water to go ahead and flow downward into their mine workings. That is the intent of setting surface pipe.

Q Also, you mentioned the potash operators coming through and pulling pillars and letting the back come in and subside?

A Yes, Sir.

Q Bo you suppose that the potash operators would be willing to conduct a selective program on pulling these pillars in areas where there are producing wells?

A Well, I don't know anything about the potash people. I feel certainly sure that if I owned the potash mines I wouldn't go ahead and pull the pillars out, especially in the area where a deep well is present. What we usually have, by the drilling of several wells of the Pennsylvanian section, that if a well were drilled to the Pennsylvanian section in any one particular area whereby mine workings were in operation, I feel reasonably sure that no one would dare pull these pillars out.

Q That is exactly my point. I wondered if that was any consideration.

A I think the discrepancy in the order, the most dangerous thing about the entire deal is to go ahead and drill a deep well to the Pennsylvanian and then have subsidence and lateral-horisontal movement. It does not mention the concern about the deep wells themselves. I believe by shearing the casing off in the deep wells is what probably will cause all the trouble.

Q I was just wondering if that was too much of a consideration, if accommodation couldn't be made by which that danger could be alleviated?

A I think that would be the concern of the potash company and the concern of the oil operator in that particular case.

MR. RHODES: That is all.

MR. MACHY: Anyone else?

by Mr. LANA: - Int. M. ZC. Co

Q You have a value for the potash in this area. Do you have a value for the oil?

A Yes, we had a value of potash as stated by the potash companies of a recovery of past experience of (154,000.00 per acre. I seriously doubt that the shallow wells in this area with the exception of the Gamay Pool, would recover more than 1,500 barrels per acre, or roughly approximately 34,000.00 per acre.

\*

Q It is our knowledge that the pillars remaining after the first extraction is about 30 or 35 percent, it would be roughly \$50,000.00?

A Yes, sir.

MR. MACEY: Mr. Rhodes?

By MR. RHODES:

Q Do you believe that possibly pulling the pillars in one area would result in horizontal movement, in some quite distant area?

A It could possibly affect it. It would have the effect of the earthquake. I understand you can drive over this particular area whereby these mining techniques were followed and see the subsidence on the surface of the ground.

Q I wonder if that is not directly over the particular area where the pillars were pulled?

A Yes, sir. I don't know the extent of the lateral movement.

MR. WEAVER: I can answer that. G. C. Weaver, representing torus ---Duval Sulphur and Potash. We have horizontal threats there as well as vertical. Just where it would show up, we can't tell. Assume we are mining at 1,000 feet, I would thoroughly expect to get horizontal displacement a thousand feet from any area we rocked. You robled car figure on about a 45 degree break there. when we talk about mining an area, when we go in and mine an area, in the first mining in the room and pillar system we extract about, well, from 50 to 75 percent of the potash present, we get subsidence. It is not enough to hinder our mining operations, however, if there are any oil and gas wells within a hundred feet of any one of those pillars, in in any one of those pillars 100 feet in diameter. I certainly wouldn't It wouldn't take much subsidence to want to be very close to it.

> ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691

shear a casing. Suppose the casing was sheared and gas and oil is escaped in the workings, how in the world would you ever replug that well? You have a loss of oil and gas which will never be recovered, and you will never recover the potash.

MR. MACEY: Does anyone have any further questions? Mr. Yates?

By MR. TATES:

Q Harvey Tates. I would like to ask the witness, Mr. Stanley, if, under the circumstances there is any long wall mining, is there any kind of pipe program that you could conceive of that could stand that shearing, so-called?

A No. I can't conceive of the oil industry inventing anything that would stand the shock of any lateral movement.

4 How is the cil industry and potash industry compatible in this area, for instance?

A I don't know.

I have a little field out there in the so-called area of the potash company. If you will recall, one potash company said they wanted no wells whatsoever drilled in this area. I would like to know how I are going to protect my leases?

A If I understand, and I believe Mr. Jack Frost with the United States Geological Survey is in the audience. If I undetstand it correctly from Mr. Frost in conversations that there are particular areas here owned by the government, whereby they do not issue any oil leases for shallow rights. That effective date was probably two or three years ago, I don't know the exact date. They do not issue any oil rights for shallow depths. It is only those that can drill who had the oil rights prior to that particular date. I wish Mr. Frest would elaborate on that subject.

MR. FROST: Jack Prost, United States Geological Survey. I believe you misunderstood some of our little discussion.

A I am sorry.

KR. FROST: There is a provision in those new leases in the potash area that my office can not approve the drilling of a shallow well without slearing it through Washington in advance.

A: I see. May I ask you a question? You can drill anywhere in the defined potash area, an oil well if you do own the oil and gas leases on Federal acreage?

MR. FROST: I think you have something mixed up there. There where is no provision that I know of we can't approve the drilling of a well with a valid oil and gas lease, but there would be areas in there where we would have to consult with the potash companies and reach an agreement between the operator and the potash company before I could approve the drilling. Does that clear it up?

A Yes.

MR. MAGEY: Does that pertain solely to shallow wells or both?

MR. FROST: No shallow, those from 5,000 feet up. If, on the new leases I would have to clear through Washington.

MR. MACEY: Mr. Yates?

MR. YATLS: I would like to ask, under the circumstances, how is a man going to get approval from the potash companies to drill a well. He says that he can't issue a permit to drill a well without approval of the potash company if they don't want any wells

drilled in their so-called A or ore body, how is a man going to get

the approval.

A I am sure they have to approve the drilling of the oil well if you conferm to Order H-111.

MR. YATES: That suits me.

MR. FROST: This may help clear that up. That oil and gas exploratory test well should not be drilled through any open potash mines or within 1,320 feet thereaf, unless agreed to in writing by the potash lessee involved. That is on your R-111, Page 7, Section 3, Exploration of Areas, and this was Area A, a portion of Subparagraph A there.

MR. MACEY: Anyone have any further questions of Mr. Stanley? Mr. Stanley, I think we have possibly gotten off the beam here a little bit. I don't think we have done any harm. It appears to me from what you have said, that you are more concerned with the deep drilling than you are with the shallow. Am I right?

A That is correct, if you take into consideration the subsidence and the pressure of the Pennsylvanian Formation.

MR. MACEY: That is all I have.

# RE-DIRECT EXAMINATION

By MR. KITTS:

4 Mr. Stanley, leaving the question of subsidence for the moment, you commented on the casing program of R-111. Would you cane to make any comment on the casing program of the Reese-Simms Oil Company?

A No, sir, I do not wish to make any comment.

MR. KITTS: That is all.

A well, I might say that they have not complied with Order

ADA DEARNLEY & ASSOCIATES STENOTYPE REPORTERS ALBUQUERQUE, NEW MEXICO TELEPHONE 3-6691 R-111, but they are here to seek an exception.

Q How would you compare the protection afforded by their casing and that afforded by R-111?

A That would be an argument to know whether that core of cement actually protects the salt section on that part of the pipe.

Q That would be the point?

A Yes.

MR. MACEY: Mr. Lane?

# RE-CROSS SXAMINATION

By MR. LANEI

Q Things have been said here, how can a potash company agree to a well, when an operator has already been put into intent that he would comply with the regulations and he hasn<sup>\*</sup>t? How can we ever agree to it before the well is drilled? We are not getting very much assurance there. He stated that he was going to comply with the regulations.

A You want me to answer that question? I don't know.

MR. MACEY: Anyone else? If not the witness may be excused.

(Witness excused.)

MEL MACHY: Does anyone have anything further in this case? If not we will take the case under advisement. STATE OF NEW MEXICO ) : ss. COUNTY OF BERNALILLO )

I, <u>ADA DEARNLEY</u>, Court Reporter, do hereby certify that the foregoing and attached transcript of proceedings before the New Mexico Oil Conservation Commission at Santa Fe, New Mexico, is a true and correct record to the best of my knowledge, skill and ability.

\$

IN WITNESS WHEREOF I have affixed my hand and notarial seal this 28th day of <u>April</u>, 1955.

Not ry Fublic, Court Reporter /

My Commission Expires:

June 19, 1955

# BEFORE THE OIL CONSERVATION COMMISSION OF THE STATE OF NEW MEXICO

# IN THE MATTER OF THE HEARING CALLED BY THE OIL CONSERVATION COMMISSION OF THE STATE OF NEW MEXICO FOR THE PURPOSE OF CONSIDERING:

CASE NO. 278 Order No. R-111-A

THE APPLICATION OF THE OIL CONSERVATION COMMISSION UPON ITS OWN MOTION FOR AN ORDER REVISING ORDER R-111 ISSUED IN CASE 278, PERTAINING TO THE POTASH-OIL AREAS OF EDDY AND LEA COUNTIES, NEW MEXICO.

### ORDER OF THE COMMISSION

#### BY THE COMMISSION:

This cause came on for hearing at 9 o'clock a.m. on July 14, 1955, August 17, 1955 and September 15, 1955, at Santa Fe, New Mexico, before the Oil Conservation Commission, hereinafter referred to as the "Commission".

NOW, on this 13th., day of October, 1955, the Commission, a quorum being present, having considered the records and testimony adduced, and being fully advised in the premises;

#### FINDS:

(1) That due notice of the time and place of hearing and the purpose thereof having been given as required by law, the Commission has jurisdiction of this case and the subject matter thereof.

(2) That the delineation of an area including and containing potential oil and gas reserves, within which are commercial potash deposits, and the promulgation of rules and regulations for the orderly development of oil and gas resources in such area known to be productive of potash is within the authority of the Commission for the protection of correlative rights, the promotion of conservation, and the prevention of waste.

#### IT IS THEREFORE ORDERED:

That this order shall be known as The Rules and Regulations Governing the Exploration of Oil and Gas in Certain Areas Herein Defined, which are Known to contain Potash Reserves. -2-Order No. R-111-A

## OBJECTIVE

The objective of these Rules and Regulations is to prevent waste, protect correlative rights, assure maximum conservation of the oil, gas and potash resources of New Mexico, and permit the economic recovery of oil, gas and potash minerals in the area hereinafter defined.

### II.

## THE POTASH-OIL AREA

(1) The Potash-Oil Area, as outlined in Exhibit A attached hereto and made a part hereof, represents the area in various part of which potash mining operations are now in progress, or in which core tests indicate commercial potash reserves.

(2) The Potash-Oil Area, as outlined herein, may be revised by the Commission after due notice and hearing.

#### III.

## DRILLING IN THE POTASH AREA

(1) All drilling of oil and gas wells in the Potash Area shall be subject to these Rules and Regulations.

(2) No wells will be drilled for oil or gas at a location which, in the opinion of the Commission or its duly authorized representative, would result in undue waste of potash deposits or constitute a hazard to or interfere unduly with potash deposits.

No mining operations will be conducted in the Potash Area that would, in the opinion of the Commission or its duly authorized representative, constitute a hazard to oil or gas production, or that would unreasonably interfere with the orderly development and production from any oil or gas pool.

(3) Upon discovery of oil or gas in the Potash Area, the Oil Conservation Commission shall promulgate pool rules for the affected area after due notice and hearing.

IV.

## DRILLING AND CASING PROGRAM

(1) For the purpose of the regulations and the drilling of oil and gas exploratory test wells, shallow and deep zones are defined, as follows:

Order No. R-111-A

(a) The shallow zone shall include all formations above the base of the Delaware sand or above a depth of 5,000 feet, whichever is the lesser.

(b) The deep zone shall include all formations below the base of the Delaware sand or below a depth of 5,000 feet, whichever is the lesser.

(2) Surface Casing String:

(a) A surface casing string of new or used oil field casing in good condition shall be set in the "Red Bed" section of the basal Rustler formation immediately above the salt section, or in the anhydrite at the top of the salt section, as determined necessary by the regulatory representative approving the drilling operations, and shall be cemented with not less than one hundred and fifty percent (150) percent of calculated volume necessary to circulate cement to the ground surface.

(b) Cement shall be allowed to stand a minimum of twelve (12) hours under pressure and a total of twenty-four (24) hours before drilling the plug or initiating tests.

(c) Casing and water-shut-off tests shall be made both before and after drilling the plug and below the casing seat as follows:

(i) If rotary tools are used, the mud shall be displaced with water and a hydraulic pressure of six! hundred (600) pounds per square inch shall be applied. If a drop of one hundred (100) pounds per square inch or more should occur within thirty (30) minutes, corrective measures shall be applied.

(ii) If cable tools are used, the mud shall be bailed from the hole, and if the hole does not remain dry for a period of one hour, corrective measures shall be applied.

(d) The above requirements for the surface casing string shall be applicable to both the shallow and deep zones.

(3) Salt Protection String:

(a) A salt protection string of new or used oil field casing in good condition shall be set not less than one hundred (100) feet nor more than six hundred

500) feet below the base of the salt section; provided that such string shall not be set below the top of the highest known oil or gas zone.

. \_ 2 (b) The salt protection string shall be cemented, as follows:

(i) For wells drilled to the shallow zone, the string may be cemented with a nominal volume of cement for testing purposes only. If the exploratory test well is completed as a productive well, the string shall be re-cemented with sufficient cement to fill the annular space back of the pipe from the top of the first cementing to the surface or to the bottom of the cellar, or may be cut and pulled if the production string is cemented to the surface as provided in sub-section IV (5), (i) below.

(ii) For wells drilled to the deep zone, the string must be cemented with sufficient cement to fill the annular space back of the pipe from the casing seat to the surface or to the bottom of the cellar; however, where the base of the Delaware Mountain Group is definable the casing rules in (IV) (3b) (i) shall apply even if the depth of the bottom of the Delaware Mountain Group is greater than 5,000 feet. For the purpose of identification, the base of the Delaware Mountain Group is hereby identified as the equivalent of the base of such formation as found at a depth of 7485 feet in the Richardson and Bass No. 1 Rodke well in Section 27, Township 20 South, Range 31 East, NMPM, Lea County, New Mexico, immediately overlying the Bone Springs formation.

(c) If the cement fails to reach the surface or the bottom of the cellar, where required, the top of the cement shall be located by a temperature or gamma ray survey and additional cementing shall be done until the cement is brought to the point required.

(d) The fluid used to mix with the cement shall be saturated with the salts common to the zones penetrated and with suitable proportions but not less than 1% of calcium chloride by weight of cement.

(e) Cement shall be allowed to stand a minimum of twelve (12) hours under pressure and a total of twenty-four (24) hours before drilling the plug or initiating tests.

(f) Casing tests shall be made both before and after drilling the plug and below the casing seat, as follows:

Order No. R-111-A

1

-5-

(i) If rotary tools are used, the mud shall be displaced with water and a hydraulic pressure of one thousand (1000) pounds per square inch shall be applied. If a drop of one hundred (100) pounds per square inch or more should occur within thirty (30) minutes, corrective measures shall be applied.

(ii) If cable tools are used, the mud shall be bailed from the hole and if the hole does not remain dry for a period of one hour, corrective measures shall be applied.

(g) The Commission, or its duly authorized representative, may require the use of centralizers on the salt protection string when in their judgement: the use of such centralizers would offer further protection to the salt section.

(h) The above requirements for the salt protection string shall be applicable to both the shallow and deep zones except for sub-section IV (3), (b), (i) and (ii) above.

# (4) Intermediate String:

(a) In the drilling of oil and gas exploratory test wells to the deep zone, the operator shall have the option of running an intermediate string of pipe, unless the Commission requires an intermediate string.

(.b) Cementing procedures and casing tests for the intermediate string shall be the same as provided under sub-sections IV (3), (c), (e) and (f) for the salt protection string.

(5) Production String:

(a) A production string shall be set on top or through the oil or gas pay zone and shall be cemented as follows:

(i) For wells drilled to the shallow zone the production string shall be cemented to the surface if the salt protection string was cemented only with a nominal volume for testing purposes, in which case the salt protection string can be cut and pulled before the production string is cemented; provided, that if the salt protection string was cemented to the surface, the production string shall be cemented with a volume adequate to protect the pay zone and the casing above such zone.

(ii) For wells drilled to the deep zone, the Hand band b production string shall be cemented with a sublating all the volume adequate to protect the pay zone and the casing above such zone; provided, that if (0,01) by Eq. ( ) in intermediate string shall have been run and name is stated to the surface, the production string shall be cemented to the surface.

(b) Cementing procedures and casing tests for the production string shall be the same as provided under sub-section IV (3), (c), (e) and (f) for the salt protection string; however if high pressure oil or gas production is discovered in any area, the Commission shall promulgate the necessary rules to prevent the charging of the salt section.

AND AND A COM t y e tra **v**. s mas se statute regard . Belene ji belj – 1 keltar belen vrono toko ostako s de la salede de la si DRILLING FLUID FOR SALT SECTION

and show the fluid used while drilling the salt section shall consist of water, to which has been added sufficient salts of a character common to the zone penetrated to completely saturate the mixture. Other admixtures may be added to the fluid by the operator in overcoming any specific problem. This requirement is specifically intented to prevent enlarged drill holes.

 $(x,y_1) = (x,y_1) + (y_1)$ 「「「「「「「」」」」」「「「」」」」「「」」」「「」」」」「「」」」」」「「」」 VI.  $_{\rm eff}$  , where  $_{\rm eff}$  is the set of the transformed state of the transformation of transforma PLUGGING AND ABANDONMENT OF WELLS

(1) All wells heretofore and hereafter drilled within the Potash Area shall be plugged in a manner and in accordance with field rules established by the Commission that will provide a solid cement plug through the salt section and any water bearing horizon and prevent liquids or gases from entering the hole above or below the salt section.

(2) The fluid used to mix the cement shall be saturated with the salts common to the salt section penetrated and with suitable proportions but not more than three (3) percent of calcium chloride by weight of cement being considered the desired mixture whenever possible.

or within a mile radius of any polesh lease LOCATION FOR WELLS

Before commencing drilling operations for oil or gas on any lands within the Potash Area, the well operator shall prepare a map or plat showing the location
-7- . Order No. R-111-A

<u>ر '</u>

of the proposed well, said map or plat to accompany each copy of the Notice of Intention to Drill. In addition to the number of copies required by the Commission, the well operator shall send one copy by registered mail to all potash operators holding potash leases within a radius of one mile of the proposed well, as reflected by the plats submitted under paragraph IX (2).

The well operator shall furnish proof of the fact that said potash operators were notified\_by registered mail of his intent by attaching return receipt to the copies of the Notice of Intention to Drill and plats furnished the Commission.

The Commission, or its authorized representative, may approve such Notice of Intention to Drill if no objection to the location of the proposed well is made by a potash operator within ten days after receipt. If the location of the proposed well is objected to by the potash operator, the matter shall be referred to the Secretary-Director of the Commission for arbitration. If a satisfactory settlement cannot be reached, the Secretary-Director of the Commission shall refer the matter to a hearing before the Commission after due notice and a decision either approving or denying the operator's plans to drill shall be entered by the Commission.

#### VIII.

### INSPECTION OF DRILLING AND MINING OPERATIONS

A representative of the potash operator may be present during drilling, cementing, casing, and plugging of all oil or gas wells within a radius of one mile of the well location to observe conformance with these regulations. Likewise, a representative of the oil and gas lessee may inspect mine workings on his lease to observe conformance with these regulations.

IX.

### FILING OF WELL SURVEYS, MINE SURVEYS AND POTASH DEVELOPMENT PLANS

### (1) Directional Surveys:

The Commission may require an operator to file a certified directional survey from the surface to a point below the lowest known potash bearing horizon on all wells drilled within the Potash Area. These surveys may be required where, in the Commission's judgment, the exact location of the well-bore must be determined in order to aid mining operations.

(2) Mine Surveys:

Within 30 days after the adoption of this order, and thereafter on or before January 31st of each year, each potash operator shall furnish two copies of a -8-Order No. R-111-A

plat of a survey of the location of his leaseholdings and all of his open mine workings, which plat shall be available for public inspection.

### (3) Potash Development Plan:

Within 30 days after adoption of this order and thereafter on or before January 31st of each year, each potash operator shall furnish two copies of a projection of development plans in the form of a plat, which plat shall be for the confidential use of the Commission and for inspection by any affected oil or gas operator. The projection shall cover not less than 3 nor more than a 5 year development program.

### Х.

#### APPLICABILITY OF STATEWIDE RULES AND REGULATIONS

All general statewide rules and regulations of the Oil Conservation Commission governing the development, operation, and production of oil and gas in the State of New Mexico not inconsistent or in conflict hereinith, are hereby adopted and made applicable to the areas described herein.

#### MINES

production of individual mines shall be held confidential and not published by the inspector unless agreed to by the operator.

History: Laws 1933, ch. 153, § 192; 1941 Comp., § 67-1902; Laws 1951, ch. 231, § 1; 1953 Comp., § 63-19-2; Laws 1963, ch. 229, § 4; 1973, ch. 218, § 48. Am. Jur. 2d and C.J.S. references. — 54 Am. Jur. 2d Mines and Minerals § 194. 58 C.J.S. Mines and Minerals § 237.

### 69-26-3. [Information at request of inspector.]

The mine operator shall at any time, upon the mine inspector's written request, furnish any reasonable information or data desired by the mine inspector.

History: Laws 1933, ch. 153, § 193; 1941 Comp., § 67-1903; 1953 Comp., § 63-19-3. Am. Jur. 2d and C.J.S. references. — 54 Am. Jur. 2d Mines and Minerals § 174. 58 C.J.S. Mines and Minerals § 237.

## **ARTICLE 27**

### General Duties of Operators and Employees in Other Than Coal Mines

Sec.

| Se        | c. |
|-----------|----|
| <u>co</u> | •  |

69-27-5. Operator's report of compensable mine accidents; contents.

prohibited.

damage to equipment, violation of

danger signs and unauthorized travel

- required. 69-27-6. Safety devices and orders; employees' duty. 69-27-3. Abandonment of mine; operator to close or 69-27-7. Misdemeanors, punishment; intoxicants,
- fence surface openings and post trespass and danger notices. 69-27-4. Gas or other serious condition; operator to

69-27-2. Presence of official with complete authority

69-27-1. Safety measures required of operators

69-27-4. Gas or other serious condition; operator to report promptly to mine inspector.

#### 69-27-1. [Safety measures required of operators.]

Every mine employer shall furnish such employment and such place of employment as shall be reasonably safe for the employees therein, and shall furnish and use safety devices and safeguards, adopt and use methods and processes reasonably adequate to render such employment and place of employment safe and shall do every other thing reasonably necessary to protect the life, health, safety and welfare of such employees.

History: Laws 1933, ch. 153, § 194; 1941 Comp., § 67-2001; 1953 Comp., § 63-20-1.

Cross-reference. — For provision that certain indemnity agreements void, see 56-7-2 NMSA 1978.

Safety statute not applicable to delinquency regarding safety practices. — Where workman has been killed or injured, delinquency of employer with respect to specific safety practices required by statute (as opposed to safety devices) does not subject employer to imposition of penalty award under safety statute (52-1-10 NMSA 1978) because safety statute does not so provide. Montoya v. Kennecott Copper Corp., 61 N.M. 268, 299 P.2d 84 (1956).

Requirement of safe place to work is not "safety device" within meaning of 52-1-10 NMSA 1978. Montoya v. Kennecott Copper Corp., 61 N.M. 268, 299 P.2d 84 (1956).

Am. Jur. 2d, A.L.R. and C.J.S. references. --- 54 Am. Jur. 2d Mines and Minerals §§ 184 to 209.

Dangerous places discovered in examination of mine, master's duty as to marking, 15 A.L.R. 1480. 58 C.J.S. Mines and Minerals § 229.

#### 69-27-2. [Presence of official with complete authority required.]

The mine operator shall at all times during the operation of the mine have a person on the ground with authority over all branches and phases of the operation of the mine during the time he is on duty. Provided, however, that nothing herein contained shall prevent the owner or operator from personally having such charge of the mine, provided he can qualify under all other provisions of this act.

History: Laws 1933, ch. 153, § 195; 1941 Comp., § 67-2002; 1953 Comp., § 63-20-2.

Meaning of "this act". — The term "this act" refers to Laws 1933, ch. 153, the provisions of which are presently compiled as 69-4-1 to 69-4-10, 69-5-2, 69-5-7, 69-5-9 to 69-5-18, 69-6-1, 69-6-2, 69-11-1 to 69-11-3, 69-12-1 to 69-12-7, 69-13-1 to 69-13-3, 69-14-1 to 69-14-17, 69-15-1 to 69-15-15, 69-16-1 to 69-16-7, 69-17-1 to 69-17-10, 69-18-1 to 69-18-14, 69-19-1 to 69-19-19, 69-20-1 to 69-20-21, 69-21-1 to 69-21-6, 69-22-1 to 69-22-6, 69-23-1 to 69-23-19, 69-24-1 to 69-24-14, 69-26-1 to 69-26-3, 69-27-1 to 69-27-7, 69-28-1 to 69-28-9, 69-28-11 to 69-28-14, 69-29-1 to 69-29-7, 69-30-1 to 69-30-9, 69-31-1 to 69-31-13, 69-31-16, 69-32-1 to 
69-32-3, 69-32-5 to 69-32-21, 69-33-1 to 69-33-8, 69-34-1 to 69-34-12 and 69-35-1 to 69-35-20 NMSA 1978. Am. Jur. 2d and C.J.S. references. — 54 Am. Jur. 2d Mines and Minerals §§ 189, 190.

58 C.J.S. Mines and Minerals § 236.

# 69-27-3. [Abandonment of mine; operator to close or fence surface openings and post trespass and danger notices.]

Upon abandonment of a mine the owner or operator must effectively close or fence off all surface openings down which persons could fall, or through which persons could enter. Upon or near all such safeguards trespass warnings and appropriate danger notices shall be posted.

History: Laws 1933, ch. 153, § 196; 1941 Comp., § 67-2003; 1953 Comp., § 63-20-3.

A.L.R. and C.J.S. references. — Liability of landowner for injury or death of adult falling down unhoused mine shaft or the like, 46 A.L.R.2d 1069.

Duty and liability as to plugging oil or gas well abandoned or taken out of production, 50 A.L.R.3d 240.

58 C.J.S. Mines and Minerals § 231.

# 69-27-4. [Gas or other serious condition; operator to report promptly to mine inspector.]

The operator shall report promptly to the mine inspector by telegraph or telephone the occurrence in and about the mines of serious outbursts of gas or other serious conditions threatening to cause the loss of lives.

History: Laws 1933, ch. 153, § 197; 1941 Comp., § 67-2004; 1953 Comp., § 63-20-4.

State mine inspector. — The N.M. Const., art. XVII, § 1, provides for the position of state mine inspector, whose duties shall be prescribed by law. See also 69-5-1 to 69-5-21 NMSA 1978. The state mine inspector is chief of the bureau of mine inspection within the mining and minerals division of the energy and minerals department. See 69-1-5 and 69-1-6 NMSA 1978. Am. Jur. 2d and C.J.S. references. — 54 Am. Jur. 2d Mines and Minerals § 194. 58 C.J.S. Mines and Minerals § 237.

### 69-27-5. [Operator's report of compensable mine accidents; contents.]

A report in writing shall be made to the mine inspector of each compensable mine accident. Such reports shall give the name, age and occupation of the injured person, the date of accident, name and location of mine, the cause of accident, actual work being performed when injured, nature or result of injury, probable length of disability; this report shall be made within one month of the date of injury.

History: Laws 1933, ch. 153, § 198; 1941 Comp., § 67-2005; 1953 Comp., § 63-20-5. Am. Jur. 2d and C.J.S. references. — 54 Am. Jur. 2d Mines and Minerals §§ 177, 194. 58 C.J.S. Mines and Minerals §§ 229, 237.

### 69-27-6. [Safety devices and orders; employees' duty.]

No mine employee or other person shall remove, displace, damage, destroy, carry off or fail to use any safety device, safeguard notice or warning provided for use in any mine employment or place of mine employment, or interfere in any way with the use thereof by any other person, or interfere with the use of any method or process adopted for the protection of any mine employee, in such employment or place of employment, or fail or neglect to follow and obey safety orders promulgated by the mine operator or the mine inspector, and to do every other thing reasonably necessary to protect the life, health, safety and welfare of employees, including himself.

History: Laws 1933, ch. 153, § 199; 1941 Comp., § 67-2006; 1953 Comp., § 63-20-6. Am. Jur. 2d and C.J.S. references. — 54 Am. Jur. 2d Mines and Minerals § 199. 58 C.J.S. Mines and Minerals §§ 229, 236.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | RECEIVED RECEIVED RECEIVED                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | RECEIVED RECEIVED RECEIVED Gentlemen:

Application is hereby made on behalf of Stolts & Company for a discovery well allowable on their Hudson Federal'\$1, located \$38.4' FNL & 1650' FWL of Section 4, Township 21 South, Range 29 East.

Details are as follows:

1. Well blew out and caught fire 9:00 A.H. 9/25/66, total depth 11,100'.

2. Well now flowing and burning an estimated 600 barrels oil per day.

3. Top pay approximately 11,065' in the Strawn.

It is believed that the well can be brought under control in the next few days and successfully completed as a producing well,

Yours very truly,

OIL REPORTS AND GAS SERVICES

X W. L. Smith

### 4-16-74 to 5-6-74

Drilled 24" hole to 249' with cable tools. Lost bit in hole, 4-29-76. Abalance of efforts to deepen. Plugged as follows: Moved cable tool back and filled hele with cuttings from 1-Y. Verbal approval received to omit surface marker. As marker would be in way of drilling operations. In the event this hole should cave in sight will be installed in top of hole. No logs were run on this well.

proposed work. If well is directionally drilled, give subsurface locations and measured and true vertical depths for all markers and zones perinent to this work.)\*

#### 4-16-74 to 5-6-74

Drilled 24" hole to 249' with cable tools. Lost bit in hole, 4-29-74. Abandoned efforts to deepen. Flugged as follows: Moved cable tool back and filled hole with outtings from 1-Y. Verbal approval received to omit surface marker. As marker would be in way of drilling operations. In the event this hole should cave in after rig has been moved out a 10' plug will be installed in top of hole. No logs worker run on this well.

300 WEST WALL, SUITE 1012 MIDLAND, TEXAS 79701 915-55 (States)

Todd "25" Federal, Well No. 1 1980' FNL & 1980' FWL Section 26, T-23-S, R-31-E Eddy County, New Mexico

Gentlemen:

As per instructions for submitting an application to drill on shore or off shore, gas or oil, or geothermal steam wells, on public domain and acquired lands, Texas American Oil Corporation answers these questions as follows:

1) Exhisting Roads: Exhibit "A" shows the exhisting roads in blue lines.

2) Planned Access Roads: Exhibit "A" shows in red lines the proposed road.

3) Loaction of Well: Shown above and also on Exhibit "A".

4) Lateral Roads to Location: None.

5) Location of Tank Battery and Flow Lines: If the above well is productive, Tank Battery and Flow Lines will be located on Caliche Pad at Well.

6) Location and Types of Water Supply: Water to be hauled.

7) Methods for Handling Waste Disposal: A reserve pit located as per Exhibit "B" will be used for handling all wastes.

8) Location of Camps: None.

9) Location of Air Strip: None.

10) Location of Rig, Mud Tanks, Reserve Pits, Burn Pits, Pipe Racks, etc.: See Exhibit "C" attached.

11) Plans for Restoration of the Surface: After drilling the well, Texas American will level all pits and location as near to original ground level as possible. This location is in an arid region on which there is very little surface grass. Page Two

12) Detailed Mud Program:

0 - 600' - Bentonite and lime.
600 - 4400' - Brine treated w/Benex to control solids. LCM for loss of fluid. (Max. wt. 10#/gal.)
4400 - 12,700' - Fresh water/w/Benex to control solids. Flosal for improved samples. LCM for loss of fluid. Start w/8. 4#/gal., increase to 9. 2#/gal. @ 8000'. Max wt. 10.5#/gal.)
12,700 - 15,500' - Fresh water w/Benex - Bentonite for vis., Barite for wt., cellex for filter loss, coustic Q-Broxin to control flow properties. (Start w/12.5#/gal. and increase as needed. Max wt. 15. 3#/gal.)

13) Blow Out Preventer: See attached Exhibit "C" for detail.

Yours very truly,

unnul

#### SUPPLEMENTAL DRILLING DATA

#### J.C. WILLIAMSON WELL #1 EP-USA

1. SURFACE FORMATION: Quaternary Alluvium

2. ESTIMATED TOPS OF GEOLOGIC MARKERS:

| Rustler Anhydrite | 350'  |
|-------------------|-------|
| Lamar             | 3110' |
| Ramsey Sand       | 3165' |
| Olds Sand         | 32201 |
| Top Cherry Canyon | 4150' |

3. ANTICIPATED POSSIBLE WATER AND HYDROCARBON BEARING ZONES:

| Fresh Water         | above 350 | feet |
|---------------------|-----------|------|
| Delaware (Oil)      | 3165-3175 | feet |
| Cherry Canyon (0il) | 4000-4200 | feet |

4. PROPOSED CASING AND CEMENTING PROGRAM:

Casing program is shown on Form 9-331 C.

Hole for surface casing will be drill to below fresh water zones. Surface casing will then be run to bottom and cemented to the surface to protect fresh water zones.

Surface casing is large enough to run 8-5/8: and 7" cave in and/or water shut-off casing strings if necessary to do so. If either or both of these casing strings are run they will be mudded in and will be pulled

10-3/4" surface casing will be cemented to the surface with class "C" cement,

7" protection casing will be cemented with 150 sacks of Class "C" cement at 3300'

4-1/2" in production casing will be cemented at total depth or shallowing if significant shows are encountered in its Middle Delaware formation

5. PRESSURE CONTROL EQUIPMENT:

Pressure control equipment will consist of a control valve and oil saver.

6. CIRCULATING MEDIUM:

This will be a cable tool hole. Water will be the drilling fluid.

## 7. AUXILIARY EQUIPMENT:

Not applicable.

8. TESTING, LOGGING AND CORING PROGRAM:

No coring is planned.

Formation tests will be made as warranted by bailing hole down and measuring fluid entry rate.

新新行 计性

J.C.Wil EP-USA

It is planned that a Gamma Ray - Sonic log will be run.

9. ABNORMAL PRESSURES, TEMPERATURES OR HYDROGEN SULFIDE GAS:

None anticipated.

10. ANTICIPATED STARTING DATE:

It is planned that operating will commence on June 20, 1981.

#### J. C. WILLIAMSON, EP-USA #1-1, 26-26-29

Telephone conversation with Mr. Williamson

9/15/81 @ 2:24 p.m. TD 3047' 10 3/4 @ 350 circ 8 5/8 @ 850, (Murdock said 1250 of 8 5/8) mud to shut off water

 $5_{2_{4}}^{1_{4}}$  @ 3000' Can not close in "Boots and Coots" has head to strip in tubing.

BHP approximately 1800#, Surface press approximately 1600#, venting  $2\frac{1}{2}$  MMCF Gas Saturday blowed out (9-12-81)

Changed out well head, will move on pulling unit and start running tubing.

9/16/81 J. C. Williamson called

Have new head on and 1 joint tubing in hole with 3 vent lines. Will strip tubing this a.m. and kill well and run  $5l_2$ " and cement back to intermediate.

J.C.W1 EP-USA

#### 9/23/81

## THE FOLLOWING CONSTITUTE MINIMUM BLOWOUT PREVENTER REQUIREMENTS

- 1. All preventers to be hydraulically operated with secondary manual controls installed prior to drilling out from under casing.
- 2. Choke outlet to be a minimum of 4" diameter.
- 3. Kill line to be of all steel construction of 2" minimum diameter.
- 4. All connections from operating manifolds to preventers to be all steel hole or tube a minimum of one inch in diameter.
- 5. The available closing pressure shall be at least 15% in excess of that required with sufficient volume to operate the B.O.P.'s.
- 6. All connections to and from preventer to have a pressure rating equivalent to that of the B.O.P.'s.
- 7. Inside blowout preventer to be available on rig floor.
- 8. Operating controls located a safe distance from the rig floor.
- 9. Hole must be kept filled on trips below intermediate casing. Operator not responsible for blowouts resulting from not keeping hole full.
- 10. D. P. float must be installed and used below zone of first gas intrusion.

> RE: Report of Blowout South Culebra Bluff No. 1 Well Eddy County, New Mexico

Gentlemen:

This letter will confirm the prior notification given to Mr. Bill Gressett (Artesia office) and Mr. Dan Nutter (Santa Fe office) on January 4, 1978, concerning the blowout and subsequent fire at the Delta Drilling Company South Culebra Bluff No. 1 Well located 1980' FNL and 1650' FEL of Section 23, T23S, R28E, NMPM, Eddy County, New Mexico.

The South Culebra Bluff No. 1 Well was spudded by Amoco Production Company on November 6, 1977, pursuant to a Drilling Contract between Amoco Production Company, as Operator, and Brahaney Drilling Company, Inc., whose address is P. O. Box 1694, Midland, Texas, 79701, as Drilling Contractor.

On November 17, 1977, at 12:00 noon, Delta Drilling Company assumed operation of the well at a depth of approximately 4400' below the surface. Rig No. 7 of Brahaney Drilling Company, Inc. continued the drilling of such well until January 3, 1978, on which date such well, at a depth of 11,769' below the surface, encountered a gas kick, blew out and subsequently caught fire.

Operations for the drilling of a relief well and efforts to gain control of the well at the surface were commenced immediately. Control equipment has been installed on the wellhead and at present gas is being flared through two lines. Arrangements have been made to sell such gas to El Paso Natural Gas Company pursuant to an emergency gas sales contract, and it is anticipated that deliveries of such gas will be commenced on or about January 25, 1978.

Additional information concerning such well is being furnished to the New Mexico Conservation Commission pursuant to your forms C-103 and C-104.

# ATTACHMENT

DRILLING AT 11,769 FEET, A HIGH PRESSURE GAS ZONE WAS ENCOUNTERED. BOP AND HYDRIL WERE CLOSED AND KICK WAS BEING CIRCULATED OUT WHEN THE AUTOMATIC CHOKE FAILED FOR REASONS UNKNOWN AT THIS TIME, ALLOWING THE FULL PRESSURE TO ENTER SEPARATOR.

7

The separator was unable to handle the full pressure and subsequently failed, which in turn disabled the choke and kill manifold. At this time the well was still unloading water and gas. The rig crew stated that they were unable to reach any of the four valves going to the manifold from the BOP to shut the well in. The crew then left the location for a place of safety. The well continued to blow gas and condensate until approximately 5:10 A.M. the following morning, at which time it ignited itself.

# Sun Puts Damaged Platform Back on Line Following Blowout

Sun Exploration and Production Co. resumed production of natural gas last week from West Cameron Block 648 platform in the Gulf of Mexico. The platform was damaged by a blowout and subsequent fire last December.

The platform's output has reached 36 MMcfd from six wells that have been reworked since the blowout. The 13well platform, which had a gross producing capacity of 95 MMcfd, was producing only 64 MMcfd prior to the blowout due to reduced sales to pipelines. Well A-1, which blew out, had been producing 8-12 MMcfd. There are no plans currently to redrill the well, which was capped, plugged and abandoned.

On completion of repairs the gross producing capacity of the platform from the 12 undunaged wells is expected to be 75 MMcfd, with production averaging 55 MMcfd, operator Sun says. Diamond Shamrock Offshore Partners Limited Partnership, which has a 38.333% interest in the platform, says capacity will be 85 MMcfd. Repairs on damaged portions of the platform's deck section are expected to be finished by year-end.

Well A-1 blew out last Dec. 4 during workover operations. The fire that ignited four days later destroyed the workover rig and drilling quarters. It was extinguished Dec. 31. The blowout was capped on Jan. 22.

Sun, with a 61.667% interest, has a temporary agreement to sell 16 MMcfd to Texas Eastern Pipeline Co., which was buying production from the platform prior to the blowout. Diamond Shamrock is selling 20 MMcfd to Bethlehem Steel Corp. and to Panhandle Eastern Pipe Line Corp., also a previous purchaser of gas from the platform.

Sun won't release information on the cost of repairing the platform and said it has no estimate as to how much gas was lost as a result of the blowout and resulting fire.

land obtained from New Mexico versity is expected to handle an 44,000 takeoffs and landings an-

g for the airport was assured when Congress approved the 1985 ntal Appropriations Bill. The meach now goes to President Reagan oproval, includes \$2.2 million that ill receive in return for the 1,667 university-controlled land at the ton site. recreation area is concerned," White said. Sen. Pete Domenici, R-N.M., and Rep. Joe

-CURRENT-ARGUS, Carlsbad, N.M., Monday, August 5, 1985

Sen. Pete Domenici, R-N.M., and Rep. Joe Skeen, R-N.M., issued a joint statement Friday announcing the plans for the airport would proceed following passage of the Supplemental Appropriations Bill.

Skeen said both the Ruidoso community and New Mexico State would benefit from the land transfer that clears the way for the airport's construction.

"New Mexico State will have the funds needed to continue its important range and Fred Heckman, chairman of the Sierra Blanca Airport Commission.

Heckman said a bipartisan campaign that included Skeen, Domenici, Gov. Toney Anaya and even the Texas congressional delegation had made the new airport possible.

Domenici said months of negotiations were required at the local, state and federal levels to assure a fair agreement between NMSU and Sierra Blanca Airport Commission.

# hite Sands Rocket Test ited For Launch Today

E SANDS MISSILE (AP) — One of two designed to conduct hysics experiments in tion with the space Challenger was schedle launched today, offi-White Sands Missile aid.

ally, the two rockets be launched Saturday e aborted due to techblems.

ils at WSMR said the ck Brant rocket lifted rssfully at 4 p.m. Satiowever, the missile's path carried it east, instead of straight up as programmed.

"The first one had to be brought down three seconds before its payload would've been deployed," said Don Montoya of the WSMR information office.

The second Black Brant, with a Nike booster, did not even leave the launch pad. The rocket's flight was scrubbed just minutes before its 5:30 p.m. scheduled launch, Montoya said, because of some problems with pressure loss.

# Oil Rig Blast Leaves Four In Critical Condition

BLOOMFIELD (AP) — Four workers of the Arapahoe Drilling Company were critically injured when an oil rig near the community of Turley exploded Sunday.

Three Farmington men were taken from the San Juan Regional Medical Center in Farmington to the University of New Mexico Hospital in Albuquerque.

Hospital officials said John Murphy, 57, was listed in critical condition with burns over 90 percent of his body. Steve Lavacek, 24, is also in critical condition with burns covering 80 percent of his body.

The third man, Ernest Jeter,

50, was listed in guarded condition with burns covering 64 percent of his body.

A fourth man was taken by emergency air transport to a Maricopa County burn center in Phoenix, Ariz. Dennis J. Martinez, 25, was reported in critical condition. A Maricopa County Medical Center spokeswoman said Martinez suffers from second- and third-degree burns on 55 percent of his body.

Company officials say they are not sure what caused the 6 p.m. explosion east of Bloomfield.

Arapahoe spokesman John Ahlm said the oil well was being allowed to burn.

rage of 800 students work at Colorado anches each summer.

Catlow said students have been workng at ranches for as long as he can renember. Although it varies at different anches, he said most students must dreds of aspens and ponderosa pines and the north fork of the South Platte River, which is just 100 feet from the main lodge. # EVALUATION OF BRECCIA PIPES IN SOUTHEASTERN NEW MEXICO AND THEIR RELATION TO THE WASTE ISOLATION PILOT PLANT (WIPP) SITE, with a section on DRILL-STEM TESTS, WIPP 31, by J. W. Mercer

By

#### R. P. Snyder and L. M. Gard, Jr.

#### INTRODUCTION

The Waste Isolation Pilot Plant (WIPP) site is located about 40 km (25 mi) east of Carlsbad, N. Mex. (fig. 1). The site geography has been described in detail by Powers and others (1978) and U.S. Department of Energy (1980, 1981). Site selection was based principally on the existence of a thick section of Permian evaporites, mainly halite. The purpose of establishing this site is to demonstrate whether or not an evaporite environment is acceptable for the disposal of trans-uranic waste generated by the Nation's defense programs.

The primary concern regarding safe disposal of nuclear waste is to isolate the waste from the biosphere until it is no longer a danger to mankind. One of the most probable methods of accidental release of radiation from nuclear waste isolated in a geologic medium is leaching and transport of the waste by moving ground water. It is therefore of primary importance to identify any potential channelways that might allow water to enter a repository site located in bedded salt of the Salado Formation of southeastern New Mexico. The presence of the thick Permian (225 m.y.) rocks attests to the fact that major dissolution of the halite by unsaturated ground water has not occurred at the WIPP site.

#### Focus of Current Study

This report describes several dissolution features in the Delaware Basin and elsewhere that have been referred to as breccia pipes. Breccia pipes (also called breccia chimneys) as they occur in evaporites are vertical cylindrical pipes or chimneys that may or may not involve more than one geologic formation. The chimneys are filled with downward-displaced brecciated rock. In this context, the rock is brecciated by having collapsed into a void at depth that was probably created by ground-water solution and removal of deep-lying evaporite or carbonate rocks in an underlying aquifer system (Anderson and Kirkland, 1980; Bachman, 1980). Such features have been described in evaporite deposits in many areas of the world.

The current study was done for the U.S. Department of Energy (DOE) in response to a suggestion that because breccia pipes are thought to be the result of deep dissolution, they may represent channelways for future ingress of ground water, and that they should be considered in risk assessment programs for the evaluation of proposed waste repositories in bedded evaporite rocks. To this end, features referred to as breccia pipes in southeastern New Mexico have been assessed in relation to the integrity of the WIPP site. Reports by Anderson (1978), Bachman (1980), and Vine (1960) described dissolution and karst features in the Pecos region of southeastern New Mexico

、「大学校教育」と言語などので、「「「「「「「「「「「」」」」

and discussed the origin and history of breccia pipes. The present report is intended to supplement these studies and provide detail that was not available to them at the time their reports were written.

Using the data from exploratory work, answers may be found to the following questions concerning breccia pipes:

- 1. Do breccia pipes penetrate through the evaporite section?
- 2. What is the physical description of a pipe?
- 3. How are they formed?
- 4. How deep do they go?
- 5. When are they formed, and are they forming at present?
- 6. Are they permeable?
- 7. Where are they formed, can they form at the WIPP site?
- 8. Do they represent a threat to the WIPP site?

#### Acknowl edgments

We thank James Walls, vice-president and general manager of Mississippi Chemical Corp., Eddy County, N. Mex., for his generous assistance and cooperation and for allowing us access to the mine. Discussions with C. L. Jones (USGS, retired) and Dennis W. Powers of Sandia National Laboratories (SNL) helped to clarify initial ideas into explainable processes.

#### STRATIGRAPHIC SETTING OF THE WIPP SITE

The WIPP site is at the northern end of the Delaware Basin of New Mexico and Texas, a sedimentary basin of Permian age which is surrounded by the Capitan Reef. The geology of the area has been described in detail by Jones (1973), Powers and others (1978), and Bachman (1980) and is only summarized here.

The stratigraphic sequence and time divisions of the rocks of southeastern New Mexico pertinent to this discussion are shown in table 1.

#### Permian Rocks

Permian rocks in the Delaware Basin are all of marine origin and they are divided into four provincial series, which are in ascending order: Wolfcampian, Leonardian, Guadalupian, and Ochoan. Only rocks of the Guadalupian and Ochoan Series are pertinent to this report.

## Capitan Limestone and Backreef Equivalents, Tansill and Yates Formations

The Capitan Limestone and its backreef equivalents, the Tansill and Yates Formations, comprise the Guadalupian Series rocks. The Capitan is the reef limestone that surrounds the Delaware Basin. The limestone is generally porous and permeable (Bachman, 1980). Submarine canyons cut through the reef and were later filled with fine-grained carbonate-cemented sand (Hiss, 1975). These deposits are much less permeable than the reef limestone and they tend to retard the migration of ground water (Hiss, 1975).

# Table 1.--Major stratigraphic and time divisions, southeastern New Mexico

(Time divisions from Berggren, 1972, and Bachman, 1980.)

<sup>1</sup>Terms in parentheses are Epochs.

 $^2$ Rocks older than the Capitan Limestone are not described in this report.
The backreef correlatives of the Capitan, the Tansill and Yates Formations, are present in the areas of Hills A, B, and C, and the Wills-Weaver pipe, but are not present at the WIPP site. These formations consist mainly of bedded limestone and interbedded sandstones over the reef in the report area.

## Castile Formation

The Castile Formation consists of several thick halite and anhydrite members (Anderson, 1972). In the basin, the Castile conformably overlies the Bell Canyon Formation and is, in turn, overlain by the Salado Formation. The Castile is about 412 m (1350 ft) thick at the WIPP site.

# Salado Formation

The Salado Formation consists of halite units interstratified with thinner beds of anhydrite, polyhalite, beds of glauberite, and potash minerals. The halite beds contain varying amounts of silt and clay and are considerably "dirtier" than the halite beds of the Castile.) Many of the anhydrite and polyhalite beds are persistent throughout the basin. These have been numbered (Jones and others, 1960) and are used as marker beds for correlation purposes. The basal unit of the Salado, where it overlies the Capitan Limestone, is the Fletcher Anhydrite of Lang (1942). Locally, the thickness of the Salado varies as the result of dissolution at the top of the formation. At the WIPP site the Salado is 603 m (1976 ft) thick.

# Rustler Formation

Where no dissolution has occurred at the top of the Salado it is overlain conformably by the Permian Rustler Formation which is also part of the Ochoan evaporite sequence. The Rustler is divided into five members which are, in ascending order, the lower unnamed member, Culebra Dolomite, Tamarisk, Magenta Dolomite, and Forty-niner Members.

The lower unnamed member is composed primarily of siltstone. The Tamarisk and Forty-niner Members are similar to each other and where unaffected by dissolution, are composed of anhydrite and minor siltstone beds. Halite is present in all three members except where it has been removed by dissolution. This dissolution is progressing from west to east across the WIPP area. These three members vary in thickness depending on the amount of halite removed by dissolution. Where dissolution has occurred, a reddishbrown silty residue remains. This dissolution has created most of the karst features described by Bachman (1980).

The Culebra Dolomite and Magenta Dolomite Members are distinctive marker beds in the Rustler Formation. The Culebra, about 8 m (27 ft) thick, is a yellowish-gray, thin-bedded, finely crystalline dolomite. Many layers contain distinctive vugs about 2-10 mm (0.08-0.39 in.) in diameter which sometimes contain selenite crystals. The Culebra is the most significant aquifer in the basin area. The Magenta is composed of alternating thinly laminated reddishbrown dolomite and gray anhydrite layers. The laminae display distinctive undulatory bedding. The Magenta is about 7.6 m (25 ft) thick in the area and is also an aquifer, although to a lesser extent than the Culebra. The average Rustler in the vicinity of the WIPP site is about 82 m (270 ft) and ranges from 11 to 146 m (35-480 ft) in thickness, depending upon the amount of dissolution that has occurred.

### Dewey Lake Red Beds

The Dewey Lake Red Beds, conformably overlying the Rustler Formation, consist of soft, thin even beds of poorly indurated reddish-brown to reddishorange siltstone and fine-grained sandstone which display numerous greenishgray reduction spots 1-10 mm (0.04-0.39 in.) in diameter. Small-scale cross laminations and ripple marks are common. Lenses of cross-laminated finegrained sandstone become more common near the top of the formation indicating that a change from marine to fluvial deposition was occurring near the end of Ochoan time. Evaporite deposits are not present in the Dewey Lake but secondary selenite fills concordant and discordant fractures. Selenite also fills partings along bedding planes. These openings were probably caused by sagging of the Dewey Lake over areas where dissolution had removed halite from the underlying Rustler Formation. The formation was eroded in pre-Triassic time and varies in thickness from zero to the west to 172 m (560 ft) to the east of the WIPP site.

### Triassic Rocks

Rocks of Triassic age lie unconformably on and overlap the Dewey Lake Red Beds. Bachman (1980, p. 26) referred the Triassic rocks in this area to the Dockum Group and that usage will be followed in this report.

1

A CALL

These rocks consist mainly of well-indurated fluvial sandstone, conglomeratic sandstone, and siltstone, most of which have been removed by erosion in southeastern New Mexico, and are irregularly distributed and preserved in the WIPP area. Although to the east in Lea County the Dockum Group is as much as 460 m (1500 ft) thick, it pinches put along a roughly north-south line that passes through the center of the WIPP site. These rocks are important to this report as they are found in breccia pipes elsewhere in the area.

### Jurassic and Cretaceous Rocks.

The area is believed to have been above sea level throughout Jurassic time and no rocks of that age are present. In Cretaceous time the area was covered by a shallow sea, but rocks of Cretaceous age are only found in collapse debris in areas of dissolution southwest of Carlsbad, N. Mex.--none being preserved in the WIPP area.

# Cenozoic rocks

Cenozoic rocks in the WIPP area include the Ogallala Formation of Miocene and Pliocene age, and the Pleistocene Gatuna Formation and Mescalero caliche. Sheets and dunes of Holocene windblown sand are scattered across the area.

# Ogallala Formation

The Ogallala Formation in southeastern New Mexico consists mainly of windblown sand on which the well-known "Caliche caprock" of the High Plains has formed. The Ogallala is not present at the WIPP site and was either never deposited or more likely has been removed by erosion. The closest outcrop of Ogallala is at "The Divide" 11 km (7 mi) east of the WIPP site.

### Gatuna Formation

The Gatuna Formation of middle Pleistocene age or older (Bachman, 1980, p. 38) unconformably overlies the Permian and Triassic rocks in the area except where absent owing to erosion or nondeposition.

The Gatuna, mainly of fluvial origin, consists of unconsolidated beds ranging from silt to gravel. Much of the Gatuna is locally derived, especially from reworking of Triassic conglomerates and caliche of the Ogallala caprock.

# Mescalero Caliche

The Mescalero caliche (an informal name) caps many of the older rocks of the area. According to Bachman (1980, p. 42) it appears to have accumulated as the C horizon of an ancient soil after deposition of the Gatuna Formation. Bachman reports that dates derived by the uranium series disequilibrium technique show that the Mescalero formed between 510,000 and 410,000 years ago.

# PREVIOUS WORK ON BRECCIA PIPES IN SOUTHEASTERN NEW MEXICO

Numerous surficial features in and near the Delaware Basin have been described as being related to dissolution of the evaporites of the Ochoan Series. Vine (1960) described four domelike features as possible pipe structures. Later work done under the direction of personnel of the SNL and the USGS during studies for the WIPP site showed that two and probably three of the four domal structures are indeed breccia pipes.

Additional surficial features have been mentioned as possible pipe structures. Reports by Reddy (1961), Vine (1963), and Anderson (1978) mention several domal structures in the basin. Vine (1963, p. B40-B41) cites 11 of these to the west of the WIPP site. Many of these domal structures were found by Bachman (1980) to be no more than caliche-capped hills carved prior to Mescalero time. The hill in the SE 1/4 sec. 24, T. 23 S., R. 29 E. was mapped in detail by Bachman (1980, fig. 20) and described as an example of ancient solution and fill structure. Another structure cited by Vine (1963) in secs. 33-34, T. 22 S., R. 29 E. was mapped by Bachman (1980, fig. 18) and drilled (WIPP 32) as part of the studies for the WIPP site (Snyder and McIntyre, 1980). No indication of dissolution in the Salado below the Vaca Triste Sandstone Member (Adams, 1944) was found. The structure is related to shallow dissolution in the Rustler and Salado Formations and not to deep dissolution. A nearby drill hole, WIPP 29 (Snyder and McIntyre, 1979), drilled to gain information for hydrologic studies in Nash Draw also showed no dissolution below the Vaca Triste.

A hill in the NW 1/4 sec. 11, T. 21 S., R. 29 E. about 1.6 km (1 mi) west of the Mississippi Chemical Corp. (MCC) main shaft was mapped by Bachman (1980) and found to have beds of the Dewey Lake Red Beds dipping as much as 19°. According to Bachman, "the Dewey Lake Red Beds which are gently folded but not brecciated," are covered with caliche. "The folds are presumed to be the result of dissolution and hydration of evaporites in the underlying Rustler Formation."

Another example of domal structure called Tower Hill, located in secs. 1, 2, 11, 12, T. 21 S., R. 29 E., has been partially penetrated by mining out horizontal rooms for use in storing blasting powder used in the MCC mine. C. L. Jones (oral commun., 1980) has stated that the bedding is nearly horizontal and undisturbed around the walls of these rooms.

Reddy (1961) studied several domelike, quasi-circular features southeast of Malaga at Queen Lake. The features are generally surrounded by hogback ridges dipping outward from the central portions of the domes. These hogbacks are nearly always the Culebra Dolomite Member of the Rustler Formation. The central portions of these domes consist of brecciated Salado and lower Rustler Formation rocks. Reddy (1961) attributed the doming to upward movement of the Salado or Castile halites, the movement being caused by differential loading of the overburden during late Pliocene or early Pleistocene time. Additional stress applied during the late Cenozoic uplifts of the Guadalupe and Delaware Mountains could have aided in accelerating the upward movement of the halite and causing the Rustler Formation to be intruded by the lower formations (Reddy, 1961, p. 71).

Bachman (1980, p. 74, fig. 15) interprets the formational history of these domes somewhat differently. He defines the features as "karst domes." Much of the area near Malaga Bend (Queen Lake locale) is underlain by chaotic breccia of the Rustler Formation. The domes have a central insoluble residue of Salado partially overlain by a brecciated cover of Rustler. The less soluble dolomites are draped around the sides of the domes. According to Bachman, the formation of these domes is related to dissolution of the soluble portions of the units and tectonism or salt flowage is not a factor. î

Lang (1947) explained Cretaceous debris found lying on the Castile near the Black River valley about 40 km (25 mi) southwest of Carlsbad as the result of collapse into a solution channel formed in the Salado Formation. This debris was washed into the channel and preserved. Subsequent erosion of the surrounding Permian (Ochoan) beds eventually left the debris scattered on the surface on the Castile Formation. There are no remnants of Ochoan rocks other than the Castile in the immediate area which implied to Lang that simple erosion of the intervening Ochoan beds was not the answer.

Bachman (1980) believes that the Cretaceous rocks were deposited on tilted and beveled rocks of the lower Rustler, Salado and Castile Formations, and the fossil debris is the remnant of that heavily eroded Cretaceous section. The debris may be the material from a shallow collapse sink which formed during Cenozoic time (Bachman, 1980, p. 84). Anderson (1981) questions this interpretation citing other Cretaceous deposits nearby that rest in younger-than-Castile depressions at stratigraphic horizons equal to the lower Salado. He also states that a "truncation surface sufficient to allow pre-Cretaceous dissolution to reach into the Castile" would dip about 19 meters

per kilometer (100 feet per mile) and because this is the present regional dip, there is no allowance for post-Cretaceous uplift.

# GEOPHYSICAL STUDIES

Numerous geophysical studies have been carried out on and around the WIPP site specifically to gain subsurface information concerning the site. Some of these surveys were designed to search for possible breccia pipes. Among these were magnetic and gravity surveys by Ferruccio Gera (1974) of Oak Ridge National Laboratory (ORNL) in conjunction with R. Hopkins of the Tennessee Valley Authority (TVA), and gravity and electrical resistivity surveys by Mining Geophysical Surveys (West and Wieduwilt, 1976) interpreted by Elliot Geophysical Company (Elliot, 1976a,b; 1977).

The resistivity surveys interpreted by Elliot (1976a,b) were run over eight suspected or known pipes. Table 2 lists the names or areas involved and the locations. Resistivity profiles across selected sites are shown in figs. 2, 3, 4. and 5. Complete profiles and technical data for all eight locations are given by Elliot (1976a). The resistivity data across Hill A shows a definite anomaly. The central part of the breccia pipe has a low resistivity that is bounded by high resistivity peaks as the survey line crosses the circular ring fault. Interpretations of the resistivity profiles along with additional data discussed later in this report have led us to the conclusion that the following are breccia pipes: (1) Wills-Weaver, (2) Hill C, (3) Hill A, and (4) Hill B. The remaining four sites are not interpreted as pipes.

Gravity surveys by Mining Geophysical Surveys (West and Wieduwilt, 1976) were run across the Wills-Weaver site, and Hills A, B, C, and D. The data were interpreted by Elliot Geophysical Company (Elliot, 1976b). Reasoning behind the belief that gravity surveys across breccia pipes would show<sup>3</sup> anomalous readings is as follows:

If the brecciated material in the pipe was not well consolidated, the additional porosity as compared to the porosity of the surrounding rocks would cause the instruments to record a gravity low across the pipe, and if the material is denser than or better cemented than the surrounding rock, a gravity high would be recorded.

Figures 6, 7, and 8 show the gravity and topographic profiles across the Wills-Weaver area, and Hill C and Hill A, respectively. Figures 6 and 8 show a definite gravity low at the Wills-Weaver and Hill A sites, but there is no such low at the Hill C site (fig. 7). Elliot (1976b, v. 1, p. 22) states that gravity data do not give a consistent gravity response across known breccia pipes; and that gravity surveys are not a definitive method for locating these breccia pipes.

Seismic-reflection data (Hern and others, 1978) were obtained across the Wills-Weaver and Hills A-B locations. Generally uninterpretable reflections came from the center of these features.

### CORE HOLES AND UNDERGROUND MAPPING AT HILLS A AND C

# Hill A

Hill A lies in the SW 1/4 sec. 35, T. 20 S., R. 30 E., about 30 km (18.5 mi) east-northeast of Carlsbad (fig. 1) and is the location of drill hole WIPP 31. It has been described in detail by Vine (1960, p. 1905) and by Bachman (1980, p. 62). The hill has a low-circular shape with relief of about 15 m (50 ft) and is about 370 m (1200 ft) in diameter. It is crossed by a spur of the Atchison, Topeka, and Santa Fe Railroad. The central part of the hill has been eroded as a shallow basin that drains to the west. The outer slopes of the hill are formed by Permian Dewey Lake Red Beds overlain by Triassic rocks and capped by Mescalero caliche which dips quaquaversally about 15° (figs. 9 and 10).

Within the basin and within a ring fault about 245 m (800 ft) in diameter lie brecciated angular rock fragments of the Triassic Dockum Group that both Vine and Bachman agree appear to have come from rock stratigraphically higher than that presently exposed outside the ring fault.

To explain the beds at the surface dipping away from the breccia pipe as shown on plate 1 (in pocket) and figure 10, a discussion of the dissolution front is needed. The name dissolution front can be applied to two different stratigraphic horizons, the Rustler Formation and the top of the Salado Formation. Work at the WIPP site and the surrounding area has shown that halite from both of these formations is being removed by near-surface dissolution. This dissolution is progressing from west to east across the Delaware Basin (fig. 9). It appears that the dissolution front is roughly wedge shaped, trending north-south, with the leading edge toward the east. This leading edge starts in the Forty-niner Member of Rustler and, as the wedge thickens, progresses downward and westward into the lower two halitebearing members of the Rustler and into the upper part of the Salado Formation. The overall appearance of this wedge of dissolution is a "stair step" arrangement dropping stratigraphically down from east to west. The leading edge in the Rustler at the WIPP site is in the southeast quarter of the site and the leading edge in the Salado is in the western side of the site.

This dissolution pattern is also present over the Capitan Limestone in the vicinity of Hill A. The geophysical logs of the two oil and gas exploratory holes (Big Eddy 17 and 78) show no probable halite in the Rustler and definite removal of halite from the top of the Salado.

Field mapping has shown the Mescalero caliche draping the outward-dipping surface of Hill A did not form on the present-dipping surface, thus, the area around and across the pipe must have been fairly level during deposition of the caliche. Only after the formation of this caliche did the removal of halite from the area surrounding the pipe cause the area to subside, which did not affect the relatively impermeable rock in the pipe. This lowering of the surrounding area has resulted in the outward dipping of the surface at Hill A. Bachman (1980, p. 42) states that the Mescalero began to form about 510,000 years ago and that the upper crust formed about 410,000 years ago. This would date the movement of the dissolution front through the area as less than about 400,000 years ago.

Figure 10.--Southwest to northeast cross section through Hill A.

# Drill hole WIPP 31, Hill A

Drill hole WIPP 31 was sited inside the ring fault zone mapped by Vine (1960) and Bachman (1980). The hole was drilled in two stages. The first 247 m (810 ft) were drilled during September and October 1978, and the hole was later (July-August 1980) deepened to 604 m (1981 ft). Only a few feet of core were taken in the upper 247 m (810 ft) of the hole. One core, from 229 to 230 m (750-756 ft), was anhydrite of the Rustler Formation, the first indication of this formation and somewhere between 8 and 94 m (25-310 ft) below its normal stratigraphic position. Table 3 describes in general the lithology of cuttings and core from WIPP 31.

It should be pointed out that although a specific rock, identifiable as the Rustler Formation, was first found at a specific depth, it does not imply that the stratigraphy is normal from that depth downward (fig. 11). In fact, rocks of the Dewey Lake Red Beds were found as deep as 503 m (1650 ft), which is about 366 m (1200 ft) below the base of the unit in the surrounding area. Fragments of the Magenta (fig. 12) and Culebra Dolomite Members (fig. 13) of the Rustler Formation were found 274-366 m (900-1200 ft) below their normal positions.

One part of the Salado Formation halite (about 12 m or 40 ft; true thickness) was the only thick recognizable part of that formation cored, but many of the anhydrite fragments and much of the reddish-brown clay probably are Salado rocks. The anhydrite, starting at a depth of 580 m (1903 ft) and continuing to a total depth of 604 m (1981 ft) is tentatively assigned to the Fletcher Anhydrite, or the base of the Salado Formation. It is the only known anhydrite in this area that is thick enough to account for the amount cored. The 50° dip noted on the laminations would give the cored interval of 24 m (78 ft) a true thickness about 15 m (50 ft). It is estimated that about 3-9 m (10-30 ft) of the Fletcher remains below total depth of WIPP 31.

Because the Tansill and Yates do not contain water-soluble evaporites, they are probably not the cause of the collapse of the overlying rocks. Below these formations is the Capitan Limestone, a somewhat soluble rock known to contain large caverns (Carlsbad Caverns). The most reasonable explanation for collapse of the rocks cored in WIPP 31 is that a large cavern formed in the Capitan, and the overlying rocks, as young as the Triassic Dockum Group, collapsed into the void. The Fletcher Anhydrite probably acted as a supporting beam over the collapse for some time, but as the cavity in the Capitan grew wider, the width exceeded the ability of the Fletcher to serve as a support, and collapse occurred. Another possible method to consider is that the cavity was filled with water to the base of the Fletcher, and declining water levels removed the bouyant support on the Fletcher. This would cause an apparent increase in weight of  $\pm 50$  percent of the Fletcher that would increase the stress and exceed the rock strength. The Fletcher is considered as the support beam rather than one of the units in the Tansill or Yates because of its lack of bedding and its intergrown crystalline structure. The Tansill and Yates are thin bedded granular rocks.

Most of the halite of the Salado Formation, and all of the halite in the Rustler Formation are missing in the core from WIPP 31. There is no Castile Formation present over the Capitan. In an oil and gas exploration hole (Cities Service Oil and Gas, Big Eddy unit 17) about 0.8 km (1/2 mi) southwest

Table 3.--Lithologic description of cuttings and core for WIPP 31--Continued

Figure 11.--Core from WIPP 31 showing block of younger Dewey Lake Red Beds underlying older fragments of Rustler Formation. The small light-gray spots in lower part of core are reduction spots. Arrows point downhole.

Figure 12.--Fragments of siltstone and anhydrite with a fragment of the Magenta Dolomite below 1627-footage mark in WIPP 31. Arrows point downhole.

Figure 13.--Breccia from WIPP 31 containing anhydrite and siltstone fragments. A fragment of the Culebra Dolomite has the depth number 1448 written on it. Arrows point downhole. of drill hole WIPP 31, there is a total thickness of at least 358 m (1175 ft) of halite in the Salado. In a second hole (Perry R. Bass, Big Eddy unit 78) about 0.8 km (1/2 mi) northeast of WIPP 31, there is over 305 m (1000 ft) of halite preserved in the Salado Formation. The missing halite (>305 m or >1000 ft) of the Salado in WIPP 31 must have been dissolved after collapse of the material in the pipe.

At some time, minor amounts of oil migrated from the Yates Formation upward into the Salado. Traces of oil found in the brecciated rock in WIPP 31 have been identified (Palacas and others, 1982) as being similar to oil from drill holes nearby that are producing from the Yates Formation. The oil stains were found in breccia (497 m or 1629 ft) consisting of siltstone, anhydrite, and dolomite fragments and a matrix of mud, recrystallized halite and glauberite crystals (rocks of the Dewey Lake, Rustler, and Salado Formations).

Results of hydrologic tests in WIPP 31 run by USGS personnel are reported in a following section. Continuous monitoring of the drilling fluid performed by Morco Geological Services to determine the presence and amounts of nitrogen, carbon dioxide, hydrogen sulfide, and hydrocarbons demonstrated that none of these gases was present in detectable amounts.

Briefly, the order of the formation of the breccia pipe at Hill A is interpreted as follows:

- 1. Deposition of rocks as young as Triassic Dockum Group.
- 2. Cavity formation in the Capitan Limestone by circulating ground water.
- 3. Collapse of the Yates and Tansill Formations into cavity.
- 4. Support by the Fletcher Anhydrite kept further upward collapse from occurring for some time.
- 5. Eventual collapse of the Fletcher and downdropping of Salado and younger units. This stage probably consisted of some massive and some fragmental downdropping.

1

- 6. Continual dissolution of Salado and Rustler halites in the pipe, possibly from downward moving water. Mud and small rock fragments in the pipe continually being carried or dropped downward during this stage.
- 7. Formation of Mescalero caliche across nearly horizontal surface.
- 8. Dissolution front removes all Rustler halite and some upper halite from the Salado from around the pipe causing near-surface beds to dip away from pipe.

# Hill C

Hill C is another dome-shaped surface feature 3 km (2.5 mi) southeast of Hill A. It rises about 30 m (100 ft) above the surrounding terrain, is roughly circular in plan, and is about 350 m (1150 ft) across. It has been breached on the west side in a manner similar to Hill A but to a lesser extent. The surface, where not eroded, is formed by draped Mescalero caliche which partially engulfs the Gatuna Formation and brectiated rock of Triassic age. The Mescalero caliche is offset slightly in several places and is displaced downward toward the center of the hill, apparently in response to

minor readjustments of the breccia mass (fig. 14). Unlike Hill A, only a very small area of Dewey Lake Red Beds is exposed in the gully that drains the western part of the hill. The rock exposed in the center of the hill is brecciated Triassic Dockum Group fluvial sandstones and siltstones.

Samples for palynomorph analyses were collected from the brecciated Dockum Group rocks and were studied by Robert M. Kosanke of the USGS. Kosanke reported (oral commun., 1981) on the findings as follows: The samples yielded few palynomorphs and they were poorly preserved. Palynomorphs are usually not found in red or oxidized rocks and the presence of calcareous matter does not normally help with the preservation. The samples did, however, yield a few poorly preserved palynomorphs. Kosanke states (written commun., 1981) "The most abundant of these would be the remains of the alga Botryococcus cf. B. braunii. Botryococcus is known to occur from early Paleozoic time to the present day where it is a member of the freshwater plankton, is widely distributed throughout the lakes of the United States, but is rarely abundant. Botryococcus is abundant and the primary constituent of boghead or algal coals known to occur in Alaska, Australia, France, Scotland, South Africa, and mainland United States. It is not so much an indicator of age as it is an indicator of freshwater environment. A single pollen grain, probably related to the Compositae was found together with two tricolpate pollen grains, and several winged pollen grains assignable to Pinus. In addition, several spores referable to the fungi were observed. This is not an assemblage--there is not enough evidence to evaluate with any degree of confidence. If what was found is valid and not modern contamination, the presence of the Compositae would suggest Oligocene or younger."

The rocks, as mentioned above, have been dated by field mapping as Triassic; thus indicating the likelihood of contamination of the samples precluding the use of palynomorphs, in this case, to date the exposed rocks in the central surficial part of Hill C.

The breccia pipe at Hill C provided an unparalleled opportunity to study a pipe in three dimensions. Prior to our investigation, this was the only breccia pipe that was known to contain brecciated rock at depth. During mining operations in 1975, in the 7th ore zone (see Jones and others, 1960, for stratigraphic location of ore zones) in the MCC potash mine one of the mine entries encountered the edge of this pipe. Not only were the rocks adjacent to the pipe exposed 366 m (1200 ft) below the surface, but also some of the breccia in the pipe itself could be studied.

The objectives of investigating Hill C were to explore and define the horizontal dimensions of the breccia pipe at mine level, and study the effects of the collapse on the adjacent rock in the MCC potash mine. Additionally, it was planned to match the underground pipe boundary with its surface expression and to identify the stratigraphic origin of the displaced rock fragments in the pipe at mine level. Additional objectives were to determine the permeability and porosity of the pipe and, if possible, the origins and ages of mineral phases associated with dissolution.

It was planned to drill horizontal core holes across the breccia pipe from the mine level to examine the breccia, determine the pipe dimensions, and collect samples that might be useful for age determination. Before these

holes were to be drilled, it was thought advisable for safety reasons to drill a vertical hole from the surface to ascertain whether the breccia contained fluids or gases that might endanger the mine if intercepted by horizontal holes. Borehole WIPP 16 was designed for this purpose and was located on Hill C (NW1/4 SW1/4 sec. 5, T. 21 S., R. 30 E.). The hole was cored from 37.5 m (123 ft) to a total depth of 396 m (1300 ft), about 27 m (88 ft) below the mining horizon. A summary of the stratigraphy for rocks recovered from WIPP 16 is given in table 4, and an abbreviated lithologic log is given in table 5.

Exploratory drill holes for potash are located in the immediate vicinity of the breccia pipe (fig. 14), and two of these are combined with borehole WIPP 16 to construct a cross section across the pipe and into the surrounding rock (fig. 15).

WIPP 16 penetrated brecciated rock of the Triassic Dockum Group, and the Permian Dewey Lake Red Beds and part of the Rustler Formation. Although the Rustler has been downdropped and shattered, the beds, unlike the overlying rocks, were in recognizable stratigraphic order. The contact of the Rustler and the overlying Dewey Lake has been downdropped about 189 m (620 ft) (fig. 15), as has the Culebra Dolomite Member of the Rustler. Halite below the Culebra was cored in WIPP 16, and this differs markedly from drill hole WIPP 31 at Hill A where no halite and ho recognizable stratigraphic sequence of rock was found to represent the Rustler.

The explanation for the nearly intact Rustler, minus halite in the Fortyniner and Tamarisk Members, in WIPP 16 is a problem. At Hill A (WIPP 31), the sequence of deposition, collapse of material in pipe, erosion, deposition of caliche, and dissolution of halites in the Rustler and upper Salado seems reasonable. To preserve Rustler halite in the pipe at WIPP 16, and arrange a plausible sequence of events for the formation of the pipe at Hill C, calls for stages of dissolution of the Rustler and upper Salado halites that suggest an unreasonable timing for the dissolution of these halites. It is probable that the formation of the pipes at Hills A and C occurred at widely spaced times.

The dipping beds shown abutting the pipe in figure 15 are explained by the following evidence. The surface dips of the undifferentiated Triassic rocks are mappable at the surface. The inward dipping rocks of MB 121 are mapped in the potash mine drift (fig. 23). Dips of beds between these two horizons and below MB 121 are hypothetical, but a reversal between the surface and MB 121 is true, and somewhere above the base of the dissolution of halite in the Salado (MB 109) is a reasonable place to put it.

Oil smears were found on core from WIPP 16, just as they were in WIPP 31. In WIPP 16 the rocks containing these smears were anhydrite, halite, and dolomite of the Rustler Formation. (Analysis of this oil was reported by Palacas and others, 1982.)

Hydrologic testing of WIPP 16 was not done because of the instability of the hole walls. A neutron log run by USGS personnel, Albuquerque, N. Mex., did not indicate the presence of water. Morco Geological Services continuously logged drilling fluids to detect CO<sub>2</sub>, hydrocarbons, nitrogen, and

hydrogen sulfide. Between depths of 362 and 367 m (1188 and 1204 ft), hydrogen sulfide was detected; the readings indicated as much as 6 parts per million between 365 and 366 m (1198 and 1200 ft). No other gases were detected in the drill hole.

In WIPP 16, all of the breccia above the Rustler Formation is composed of Triassic Dockum Group and Permian Dewey Lake Red Beds. Some idea of the minimum thickness of these units at the time of collapse of the material into the pipe can be estimated. The present thickness of these two units in the pipe is about 350 m (1150 ft). These units without collapse are about 145 m (475 ft) thick in nearby drill holes. Using an approximate bulking factor of 1.25, averaged from those of Houser (1970) for alluvium and zeolitized bedded tuff at the Nevada Test Site, the expected thickness of the brecciated rock in the pipe would be about 181 m (595 ft). This is about half (181 versus 350 m; 595 versus 1150 ft) of what is present. Apparently there was another  $\pm 145$  m (±475 ft) of Dockum Group rock overlying the present Dockum Group. Following this line of reasoning, the collapse may have occurred at a time when a more complete sequence was present. The core from WIPP 16 contained no voids, but rather a great deal of fine sediments, mostly clay and silt-size material. This filling would have been obtained from disintegrated fragments of collapse material, and this would lower the bulking factor to something less than 1.25 and thereby require an even thicker section of rock than the extra  $\pm 145$  m  $(\pm 475 \text{ ft})$  at the time of collapse.

This estimation technique cannot be used in WIPP 31 because the loss of halite in the Salado and Rustler Formations adds too many variables to the calculations. Unfortunately, there is no way of estimating the erosional rate of the Dockum Group rock, but it must have taken hundreds of thousands of years to remove most of the rock. The Dockum Group is about 220 m (720 ft) thick 26 km (16 mi) to the east of Hill C, and thicknesses of over 457 m (1500 ft) are found farther east.

During this stage of the collapse, a depression probably formed at the surface allowing surrounding Triassic surface material to be washed into the depression. This material, especially the smaller fragments of sandstone and siltstone, was carried downward to form the matrix of the brecciated material now found in the pipe.

### Underground Exploration

In doing development work to open another area of the 7th ore zone in the MCC potash property for mining, entries were driven to the northwest from the main haulage entry (fig. 14). In the MCC mine, the 7th ore zone dips gently northeast. As the new entries were advanced northwestward and approached the breccia pipe, the ore zone began to dip down at a steeper angle than the mining machine could follow, so the machine mined progressively higher and higher beds (figs. 16 and 17) until the edge of the pipe was reached (fig. 18). Mining exposed about 19 m (63 ft) of stratigraphic section above the 7th ore zone in a horizontal distance of 44 m (145 ft) (fig. 8). Mining was advanced about 5.5 m (18 ft) into the breccia pipe and a horizontal exploratory hole was drilled 10.7 m (35 ft) into the pipe and still encountered breccia. The hard polyhalite marker beds above the 7th ore zone

Figure 16.--Left rib of 16-L drift, breccia pipe to right of photo. Back of drift shows at top of picture. The light bands dipping about 23° to the right are the anhydrites of MB 122. The dark band at the lower right (NW) is a very argillaceous halite capped by a 0.3-m- (1-ft-) thick clay seam. Dark left edge of picture is an offset room 23 m (75 ft) from pipe edge. Arcuate striations on all pictures are caused by mining equipment.

Figure 17.--Left rib of 16-L drift as in figure 16. **B**ase of MB 120 is slightly below the center of photo, top of MB 120 is near upper left corner. Dark portion of picture to right is oil stain. Pipe about 5 m (16 ft) to right.

Figure 18.--Left rib 16-L drift. Pick leaning on breccia pipe material. Boundary of inplace halite and breccia of pipe is line that starts at base of oil stain in lower left corner, passes just above hammer handle and reaches top of photo near center. The line is a clay-filled (not gouge) fault zone. The fragments of anhydrite, polyhalite, and halite to the right of the fault show as various shades of gray. P=polyhalite, A=anhydrite. (Nos. 120, 121, and 122) and the blocks of anhydrite and polyhalite (figs. 19 and 20) in the breccia caused so much difficulty for the mining machinery that mining in that direction was discontinued.

Developmental mining was continued by driving the entry to the northeast for 183 m (600 ft) and then proceeding northwest again in order to bypass the breccia pipe. Here again the ore zone was found to dip more abruptly and steeply than the machine could follow. In this case the beds also dipped down toward the pipe, but the pipe now lay to the southwest of the newly mined entry. The ore zone disappeared beneath the floor for a distance of about 76 m (250 ft) and the drift exposed about 3 m (10 ft) of the stratigraphic section above the ore zone (fig. 21). To the northwest along the new entry, the ore zone rises to its normal altitude again and the regional dip resumes. This perturbation of the regional dip is also shown by the structure contours in figure 22. It is assumed that the dip of the beds in the bypass drift, which is very abrupt, is in response to collapse of material into the pipe which lies to the southwest of that entry. No faulting is seen in this entry or in a small diameter core hole that SNL drilled horizontally towards the pipe for 19.5 m (64 ft).

Permission was granted by the MCC for USGS personnel to do underground mapping and for SNL personnel to perform several experiments in the vicinity of the pipe in order to determine the shape and dimensions of the pipe. Two underground radar studies were done by personnel of SNL and by Dr. Robert R. Unterberger of Texas A&M (Unterberger, 1981). The purpose of these field studies was to attempt to outline a portion of the breccia pipe wall by recording return signals from the radar. The radar experiments were not successful in delineating the breccia-pipe boundary. Geologic mapping of the mine entries in the vicinity of the breccia pipe was done in February 1980 by preparing profiles of the ribs (walls) to show as much stratigraphic and structural detail as possible (fig. 23). The mapping was supplemented in several places by augering upward through the back (roof) to probe for certain marker beds. The auger and crew were furnished by the MCC.

Mapping showed that not only had the strata of the Salado Formation on the south side of the pipe been bent downward by the collapse but also the beds are displaced downward toward the pipe about 5 m (17 ft) by a nearly vertical peripheral fault 43 m (140 ft) from the pipe (fig. 24). This faulting and the downbowing of the beds suggest that the underlying chamber into which the rocks collapsed may have been larger in diameter than the present diameter of the pipe at the surface.

Oil seeps were encountered in the mine (fig. 23) near the breccia pipe in drifts 15-L and 16-L. Most of this oil was seeping from the fault 43 m (140 ft) from the pipe and moving along bedding planes, especially where polyhalite and anhydrite beds intersected the fault. Analysis of this oil and that from the horizontal drill holes is reported by Palacas and others (1982).

#### Horizontal Coring Underground

Using a portable drilling assembly designed and built by SNL personnel, three horizontal core holes were bored from mine level toward the breccia pipe (fig. 25). The plan was to intersect the pipe at the three localities. The

J

holes were cored in alphabetical order (A, B, C); the core was 2.5 cm (1 in.) in diameter. Hole A penetrated the pipe boundary. Figure 26 shows about 1.8 m (6 ft) of core at the "bottom" of drill hole A. The discing of the core was caused by torque and direct pressure on the bit face and the discs varied from about 3 mm to 10 cm (1/8 to 4 in.) in length. Argillaceous halite and anhydrite layers made up the longest lengths.

In the next to the bottom row of core in figure 26, just in from the left side is the clay seam contact 24.7 m (80.9 ft) between the normal stratigraphy and the breccia pipe. In the bottom row of core, the shades of gray are fragments of halite and anhydrite in a brown clay matrix. The black disc in the second row left is an oil-stained halite. Figure 27 is a geologic cross section of the hole.

Hole B (fig. 25) was cored to a length of 18.3 m (60.1 ft). The core in the first four rows in figure 28 was shattered during drilling, less pressure was applied to the bit during coring of the rock in the last two rows. Oil stained the lower 0.4 m (1.4 ft). The oil caused a lack of circulation of the air cooling the bit and hindered removal of the cuttings below 17 m (56 ft) and the bottom 1.2 m (4.1 ft) of core was lost. The pipe boundary was not reached. Oil from this hole was described in Palacas and others, 1982. Figure 29 is a geologic cross section of the hole.

Hole C (fig. 25) was drilled slightly up from horizontal to a length of 19.6 m (64.15 ft). No recognizable lithologic units were penetrated. Clay was penetrated in the last 0.6 m (2 ft) of the hole and the bit and pipe were jammed in place. A total of 14.6 m (48 ft) of drill pipe was recovered, leaving 7.3 m (24 ft) in the hole. It is not certain whether or not this clay represents the pipe boundary; the SNL drillers believe that the rock being cored just before the pipe became stuck was drilling like halite and not like the breccia material in drill hole A. The pipe boundary was predicted several tens of feet beyond the end of drilling. Figure 30 is the geologic cross section of hole C.

The question of whether or not the walls of the breccia pipe are vertical or the pipe is a cylindrical-shaped body cannot be fully answered with the available data. Superimposing the surface trace of the pipe with the one area underground shows that the underground boundary of the pipe is about 30 m (100 ft) further to the southeast than the corresponding part of the pipe at the surface. This could indicate that either the pipe does increase in diameter with depth or if it is a cylinder, then the cylinder is not in a vertical orientation.

In studies done by Piper and Stead (1965, p. 34), it was found that most collapse structures over underground nuclear tests are roughly cylindrical. In additional studies on the same subject, Houser (1970) used a cylindrical shape in his interpretations, although he states (p. 51) that while evidence points to the cylindrical shape in some cases, other cases indicate an inverted cone (opening downward).

Landes and Piper (1972) in studies of brine cavity subsidence in Michigan, state that surface features outside the collapse area do not extend

-----

outward farther than the underground solution cavity. This implies that the possible shape of the collapse structure is an inverted cone or a nearly vertical cylinder.

Eck and Redfield (1963) in their study on the Sanford Dam near Borger, Tex., report numerous filled chimneys having irregular vertical sides (p. 56). The upper portions of these chimneys have funnel shapes.

The general shapes of the breccia pipes at Hills A and C are believed to be near-vertical cylinders, possibly widening slightly with depth.

## OTHER SUSPECTED PIPES IN DELAWARE BASIN

## Wills-Weaver Pipe

In the earlier discussion of geophysical studies carried out in the basin for the WIPP site, the Wills-Weaver area was mentioned. A hole was drilled in sec. 12, T. 20 S., R. 29 E. and penetrated 250.2 m (821 ft) of brecciated rock. Interpretation of geophysical surveys, namely electrical resistivity (Elliot, 1976a) and gravity surveys (Elliot, 1976b), were run across the area and both gave anomalous readings across the suspected pipe. No other work has been done at this site. It is believed to be a breccia pipe. The hill over the pipe has not been breached by erosion and no near-surface structure can be seen.

## Hill B

Hill B lies immediately south of Hill A (fig. 9) and rises 28 m (93 ft) above the surrounding terrain. It is round in plan, dome shaped and caliche capped. The hill is only slightly eroded on the west and south sides where some brecciated Triassic rocks (Bachman, 1980) are exposed, but no ring fault has been seen.

Electrical resistivity (Elliot, 1976a) and gravity (Elliot, 1976b) surveys give anomalous readings across the hill much like at Hill A. No drilling was done on Hill B, but the data of Bachman and Elliot strongly suggest that this hill marks the location of a breccia pipe.

#### WIPP 13 Area

An electrical resistivity survey (Elliot, 1977) across an area about 2.4 km (1 1/2 mi) north-northwest of the center of the WIPP site indicated a possible breccia pipe area. The resistivity signature across this area appeared much like those signatures across Hills A and C. In 1978, interpretation of a gravity survey across the area indicated a gravity low centered on the WIPP 13 site (L. J. Barrows, SNL, oral commun., 1981). There is no topographic expression, of either a hill or a depression; but because of the closeness of this area to the actual repository location, further exploration was needed. Drill hole WIPP 13 is located near the center of the resistivity anomaly. Core and cuttings, along with downhole geophysical logs indicate that no buried structural anomalies exist at the WIPP 13 location (Gonzales and Jones, 1979) to account for the resistivity anomaly. The probable cause for the anomaly is an increase of sandy, more porous material in the Dewey Lake Red Beds containing more water than is found in the surrounding area. WIPP 13 was later deepened from its original depth of 311.2 m (1021 ft) to about 1279.0 m (3868 ft) to study the structure in the Castile Formation.

#### WIPP 32 and WIPP 33

About 17.6 km (11 mi) west-southwest of the center of the WIPP site is a small topographic high which was described by Vine (1963) as an elongated domal structure. Rocks of the Rustler Formation are exposed at the surface. Drill hole WIPP 32 was located on this structure. Most of the soluble rocks of the Rustler, as well as the halites in the upper 34.7 m (114 ft) of the Salado Formation, have been removed by ground water. Below the Vaca Triste Sandstone Member in the Salado, a normal undissolved section was penetrated (Snyder and McIntyre, 1980). Bachman (1980) states that the brecciated Rustler and Salado rock in drill hole WIPP 32 is the result of blanket dissolution in the area, and the fact that the feature is not related to deep dissolution below the Salado precludes it from being a breccia pipe. The feature is called a karst mound by Bachman (1980, p. 78), and is primarily an erosional feature.

A small closed depression about 4.8 km (3 mi) northwest of the center of the WIPP site was found to contain an unusually thick amount of fill material (G. O. Bachman, oral commun., 1980). The sink might be the surface expression of a breccia pipe. WIPP 33 was drilled and cored in the depression to a depth of 256.0 m (840 ft). Below the thick fill (13.4 m or 44 ft), including artificial fill for drill pad, a normal stratigraphic section was found (Snyder and McIntyre, 1981). Dissolution residues in the Rustler Formation and the upper 0.3 m (1 ft) of the underlying Salado Formation were expected as the drill hole is located just east of Nash Draw and in the area where this dissolution has been found in other drill holes (Bachman, 1980). No breccia associated with pipe structures was found in WIPP 33.

#### PIPELIKE FEATURES IN OTHER AREAS

Pipelike structures have been studied and mapped in a number of places in the world. All of these structures are in areas that have evaporites in the subsurface.

#### South Dakota and Wyoming

In South Dakota and Wyoming, studies of the Minnelusa Formation by Bowles and Braddock (1963) show that the Minnelusa (Permian-Pennsylvanian), composed of limestones and gypsum has undergone dissolution and brecciation. The overlying rocks, as much as 305 m (1000 ft) thick, have been affected and blocks of the Minnelusa Formation have dropped as much as 45.7 m (150 ft). The unit underlying the Minnelusa is a sandstone that has undergone only minor boxwork weathering. Blocks of the overlying Opeche (Permian) and Spearfish (Permian-Triassic) siltstones are found incorporated in the breccia.

Solution that formed these pipes started in Tertiary time, proceeding downdip from surface exposures. Some pipes started development in Holocene time and are 73 m (240 ft) deep and 18 m (60 ft) in diameter. Analysis of water samples from springs and wells indicates that dissolution is continuing at the present time. In a report by Brobst and Epstein (1963, p. 331), pipes "tens to hundreds of feet in diameter" and 61 m (200 ft) deep were mapped in the Fanny Peak quadrangle of Wyoming and South Dakota. The authors attribute the pipe formation to the solution of anhydrite and gypsum in the Minnelusa Formation. Fragments of overlying Permian rocks are incorporated in the breccia in the pipes. The formation of these pipes started after the Black Hills uplift (Late Cretaceous-Early Triassic), and the dissolution is continuing to the present.

In the Wyoming-South Dakota area, the anhydrite-gypsum layers of the Minnelusa and overlying Opeche and Spearfish Formations are the rocks involved in the dissolution. Halite also was and is being dissolved from the formations as indicated by analysis of well water in the area. Brobst and Epstein (1963, p. 336) attribute the near-vertical orientation of the pipes to their formation at intersections of joints. They also postulated that most of the pipes have their roots in the Minnelusa, although some may be rooted in the underlying Pahasapa. The breccia in the pipes has been well-cemented by  $CaCO_3$ , and the pipes stand out on cliff faces and as small hills above the surrounding terrain.

#### Michigan

Michigan also contains breccia pipes. Landes and others (1945) describe the occurrence and possible formative history of these pipes in the Mackinac Straits area. They attribute formation of the pipes to cavity forming in the evaporite-rich Pointe aux Chenes Formation (usage of the Michigan Geological Survey) of Silurian age. In the subsurface the formation is called the Salina. No brecciated rocks have been found in the underlying Niagara Formation, and Landes and others put the base of the pipes in the Pointe aux Chenes.

Several previous explanations for the forming of the breccias are given in the Landes report. He and the other authors favor a solution to-cavity tocollapse of overlying rocks theory. Whether or not the collapse was catastrophic and occurred as a single event is unknown. Landes believes that some of the process involved catastrophic collapse, because brecciated rocks of much younger age are found in the breccia mass. Downward displacements of from 183 to 457 m (600 to 1500 ft) are recognized in a quarry at Calcite, Mich. (Landes and others, 1945, p. 129). Landes and others (p. 134) described these breccias as a conglomeration of rock fragments of every degree in size with interstices between the larger fragments filled with smaller fragments which range downward from a few inches to dust size.

Where calcium carbonate was available in the water moving through the brecciated rocks, they are firmly cemented by calcite. Other pipes have little cement if their matrix contains shale which filled the interstices between the limestone blocks and impeded the flow of ground water.

The age of the brecciation has been estimated by Landes and others (1945, p. 136-137). The youngest rock found in the breccia masses is the Detroit River Formation of Devonian age. These rocks must have solidified prior to collapse or they would not form discrete blocks in the breccia. At a quarry in Calcite, Mich., the flat-bedded Dundee Limestone (Devonian) can be seen overlying the brecciated Detroit River Formation. Collapse and brecciation must have been completed before the Dundee was deposited. Collapse could have

The before late Pleistocene and the outer COllapse . about 13,600 years ago. collapse for the two cylinders is about 58-73 m (190-240 ft) (Christiansen, 1971, p. 1511-12).

Figure 31 is a diagram by Gorrell and Alderman (1962, p. 307) that can, with modification, explain the anomalous structure of the breccia pipe at Hill C in New Mexico (fig. 32), where beds in the subsurface dip toward the pipe and those at the surface dip away from the pipe. In comparing these two figures, the caliche in figure 32 could be substituted for the Jurassic in figure 31 to explain the outward dipping of the surficial rocks at Hills A and C.

П

Dissolution in the Venn area may be the result of the porous Winnipegosis reef acting as a channelway for freshwater to reach the overlying salt and cause local dissolution (Bishop, 1954, pl. 1 and fig. 4; Gorrell and Alderman, 1962, p. 311).

#### Germany

Numerous collapse structures in the Zechstein area of Germany have been described by Prinz (1973), Bernhard (1973), and Grimm and Lepper (1973), among others. The surface expressions of these structures are nearly always depressions. The collapsed rock at the surface, the Bundsandstein of Triassic age, overlies the halite of the Zechstein (Upper Permian). Grimm and Lepper (1973) cite examples of breccia-filled pipes in the Solling Arch in the Bundsandstein 750-950 m (2460-3117 ft) above the Zechstein salts. The diameter of these sinks ranges from 20 to 250 m (66-820 ft). There is no soluble material in the Bundsandstein, and the inference given by Grimm and Lepper is that the pipes go downward to the Zechstein.

Bernard (1973) describes an area 25 km (16 mi) northwest of Kassel, FRG having collapse sinks now filled with rocks of Keuper and Muschelkalk (Triassic) age. These sinks are in rocks of the Lower Muschelkalk (Middle Triassic) which overlie the Bundsandstein. He attributes the collapse to the

Bernard believes that the Zechstein at the locations of these pipes contains little halite; the edge of the Zechstein is in this area, and therefore could not be the root zone for the pipes. He does acknowledge the existence of Zechstein rooted sinks 25 km (16 mi) to the north of Kassel in the "Cloudburst" area of Tendelburg. Bernhard (1973) dates the formation of the pipes near Kassel as late Tertiary to early Quaternary on the basis of the sink-fill material containing Keuper rocks (Upper Triassic).

#### CONCLUSIONS

## Method(s) of Formation of Breccia Pipes and Age of Formation of Known Pipes in Basin Near the WIPP Site

The understanding of the method(s) of formation of breccia pipes in the Delaware Basin is critical to the placement of a repository for radioactive waste at the WIPP site. The principal question is: Can a pipe develop under the repository and cause a breach in the system that will allow access of fluids to the waste canisters? A secondary question is: Could a nearby developing pipe adversely affect the repository? Investigations at and near the WIPP site have helped to define what a breccia pipe is and how a pipe develops, but not what governs its location--see below. Another question is: Can dissolution of beds affect the integrity of the repository?

Examples of pipes in Michigan show that at some stage in the development of those pipes there was catastrophic collapse. In the Mackinac Straits region of Michigan, breccia fragments have been identified 183-229 m (600-750 ft) below their normal stratigraphic horizon (Landes and others, 1945, p. 129). Limestone beds above the cavities where halite had been dissolved could have formed support beams which held until increasing widths of the cavities caused failure of the beams, at which time the material above the existing cavities could collapse rapidly, causing a jumbling of material in the collapse chimney.

Rock in core from WIPP 16 and WIPP 31, drilled into known or expected breccia pipes north of the WIPP site in southeastern New Mexico, also shows a great deal of intermingling of various strata. Dolomite fragments have been found 335 m (1100 ft) below their normal stratigraphic position in WIPP 31. Siltstone fragments in WIPP 16 are found 183 m (600 ft) below their expected level.

Depending upon the type of rock above the solution cavities, the downward movement of the overlying rocks can be catastrophic as in the above cases, or slowly as in many salt mines (actually as salt flowage). If the movement is slow or in the catastrophic cases if the drop is not far, the falling rocks will fracture but not be mixed and jumbled with surrounding lithologies.

The only known breccia pipes in the Delaware Basin in the vicinity of the WIPP site are located 19-32 km (12-20 mi) northwest of the center of the site. Two pipes, and probably a third, have surface expressions which are nearly circular, rounded and breached hills 15-30 m (50-100 ft) in elevation. These are Hills A, B, and C of Bachman (1980) (domes A, B, and C

of Vine, 1960). Relief of a fourth pipe, the Wills-Neaver, is not as high, 5 m (15 ft), and is not breached to allow parts of the inner near-surface rock to be seen. All of these locales are over the buried Capitan reef.

Numerous other small hills and sinks in the Delaware Basin have been investigated to see if they are surface expressions of breccia pipes. Geophysical work, electrical resistivity and gravity surveys, as well as surface geologic mapping, suggest that all but the above four mentioned locations are caused by other types of solution of evaporites. Bachman (1980) describes the features as karst domes (Malaga Bend area, southeast of Carlsbad), karst mounds (WIPP 29, WIPP 32 drill-hole areas) and solution and fill structures (hill about 4.8 km or 3 mi) east of southern end of Laguna Grande de la Sal. All of these features are formed by near-surface dissolution of evaporites and do not have a deep-rooted base below the upper part of the Salado Formation.

The method of formation of the breccia pipe at Hill A can be partially reconstructed from the core of drill hole WIPP 31 and the cross sections constructed through the pipe using subsurface data from oil and gas exploratory holes (fig. 10). Initially, a cavern must be formed in some unit at depth. The only rock still below the bottom of WIPP 31 (604 m or 1,981 ft) that contains a great deal of soluble rock is the Capitan Limestone. Ground water moving through the Capitan could cause extremely large caverns to form. Bretz (1949) attributes the formation of Carl\$bad Caverns and numerous nearby caves to phreatic conditions. Jagnow (1979) believes that the caves were formed under vadose conditions and only exfoliation and speleothem development modified them to their present shapes. Both authors agree that the major portions of the caves formed during and after uplift and northeastward tilting of the Delaware Basin during late Pliocene time.

The ground-water history during the late Pliocene tilting is unknown. In the area of Hills A and C, ground water must have moved through the fractured Capitan, dissolving the limestone along fracture sets similar to solution phenomena along the uplifted portions of the reef on the western edge of the basin. This dissolution could have caused the formation of caverns in the Capitan Limestone into which overlying rocks could collapse.

Above the Capitan Limestone at Hill A are the Yates and Tansill Formations, consisting of interbedded sandstones, siltstones, and dolomites. The soluble carbonates in these formations are not thick enough to account for the cavity size necessary to cause the massive collapse of the rocks above them. Core from the bottom part of WIPP 31 consisted of anhydrite, broken and rehealed, not jumbled, and dipping about 50°. This mock is tentatively assigned to the Fletcher Anhydrite. It is the only known anhydrite bed thick enough to account for the approximately 15 m (50 ft) (true thickness) of anhydrite in the drill hole. Using the projected depth at which the Fletcher should have been encountered (fig. 10), a drop of about 76 m (250 ft) occurred. During the early formation of the Hill A pipe, the collapse may have been a slow process with the Tansill and Yates dropping into the cavity forming in the Capitan Limestone until the thick beam of the Fletcher was reached. This unit could act as a support beam holding up the overlying rocks until the cavity below reached sufficient horizontal spread that the beam failed. At this time, the Fletcher could have dropped the complete 76 m (250 ft) at one time, allowing some of the overlying halite and thin anhydrite and

polyhalite beds of the Salado Formation to drop with it. Rocks of the overlying Rustler Formation, Dewey Lake Red Beds, and Dockum Group may have also dropped.

The cavity would be filled with unsaturated water and as the mass of rock dropped nearly instantaneously into the cavity, the water would be forced out. The easiest path would be upward into the void and fractured rocks created by the collapse. Much of the halite would be dissolved by this water and eventually the now saturated water would move downward and out through the existing paths in the reef.

It is doubtful if collapse to the surface occurred all at one time. The mixture of rock units, with some rocks dropping as much as 335 m (1100 ft) to be mixed with rocks from a lesser vertical drop, implies that there were several stages of collapse as the pipe stopped its way to the surface.

Boulders of Dockum Group conglomerate now present on the surface overlying the pipe are believed to come from a higher stratigraphic position (Bachman, 1980, p. 67). The presence of these younger rocks implies that the Dockum Group was thicker at the time of formation of the pipe than it is now.

After the collapse to the surface, the resulting depression served as a catchment basin, and as the collecting water percolated downward, it also dissolved halite, potash, and other soluble rocks. Nearly all of the Salado halite and all of the Rustler halite was removed by this process aiding additional collapse in the pipe. This process also transported clay, silt, and sand downward and these particles became the matrix of the brecciated rock in the pipe.

Complete removal of soluble rocks has not occurred in the pipe filling at Hill A. Evidence of this is found in the anhydrite and gypsum fragments and beds still present, and in the large block of Salado halite cored between depths of 444 and 464 m (1458 and 1522 ft). Additional evidence of the incomplete removal of solubles is found in fragments of the Dewey Lake Red Beds. Stringers of selenite (gypsum) are found cutting these fragments but not the breccia matrix. Selenite stringers are found in the Dewey Lake Red Beds where the unit has not been brecciated. These deposits are thought to be caused by downward percolating of calcium sulfate-enriched water filling bedding-plane partings and fractures caused by gentle subsidence of the rock as units below are slowly being dissolved. This process is occurring or has occurred in much of the Dewey Lake Red Beds on the western half of the WIPP site (Jones, 1978) to the south of Hill A.

Over some period of time, surface erosion removed the Dockum Group rocks and any depression over the sink was filled in by debris-carrying surface water. About 600,000 years ago the Gatuna Formation was deposited across a gently rolling terrain filling in lows in the topography. Above the Gatuna, the Mescalero caliche was deposited on a nearly flat surface (410,000-510,000 years ago, Bachman, 1980). The caliche was deposited over the pipe at Hill A. The present dip of the caliche beds away from the center of Hill A indicates removal of halite from around the pipe. Holes drilled nearby show that the Rustler halite and the upper part of the Salado halite have been removed. This removal is referred to as the dissolution front (see p. 18), a wedge-shaped subsurface solution process, proceeding from west to east across the area. The presence of the Mescalero caliche at Hill A indicates that the dissolution front passed through the area less than 500,000 years ago. This process of dissolution around the margins of the pipe accounts for the outward-dipping beds.

Hydrologic tests (see section on Drill-Stem Tests, WIPP 31, this report) show that the pipe material is not capable of transmitting ground water. The clay matrix surrounding the rock fragments acts as an impermeable barrier, and so there is probably no additional dissolution of evaporitic rocks in the pipe; at least in the upper 549 m (1800 ft) above the massive anhydrite found at the bottom of drill hole WIPP 31.

The breccia pipe at Hill C exhibits much the same history of formation as the one at Hill A. In addition to a drill hole into the pipe from the surface, there is the added feature of a mine drift that penetrates a few feet of the pipe on the southeast side about 366 m (1200 ft) underground (MCC drifts 15-L and 16-L and a drift that bypasses the pipe on the northeast side). Both of these areas underground show that the strata of the surrounding rocks dip in toward the pipe. These dip directions are just the opposite of the ones at the surface of both pipes where the dips are outward. The reversal of dip is attributed to the following: during initial collapse of the material in the pipe, the surrounding beds were dragged downward toward the pipe; subsequent dissolution of upper strata, namely the Rustler halites above the Culebra Dolomite Member, as the dissolution front moved from west to east across the area, lowered the upper few hundred feet of the surface surrounding the pipe, causing the near-surface beds to dip away from the pipe.

To a depth of about 350 m (1148 ft) in drill hole WIPP 16 at Hill C, breccia fragments of the Dewey Lake Red Beds and the Dockum Group make up the material in the pipe. The first anhydrite of the Rustler was cored at 350 m (1148 ft), and from this depth to total depth (396 m, 1300 ft) a nearly normal section of Rustler was cored. The beds were dipping about 35°, indicating some tilting of the beds after coming to rest. These Rustler rocks are fractured but not jumbled lithologically like the overlying Dewey Lake Red Beds and Dockum Group rocks. Both marker dolomite beds are present in the core. Below the lower dolomite (Culebra), the drill hole penetrated halite beds normally found in the Rustler. Halite beds between the dolomites and above the upper one (Magenta) are missing and only an insoluble residue is left. This indicates that the dissolution front had not reached the halites below the Culebra at the time of the collapse at Hill C. This differs from Hill A where no halites were found that could be identified as Rustler.

The total depth of WIPP 16 (396 m, 1300 ft) is about 24 m (80 ft) below the drift in the mine. Rocks of Rustler were cored in the bottom part of WIPP 16, but in the wall of the pipe in the mine are rocks of probable Salado. These rocks include large blocks of anhydrite that could have come from MB 103 or 109, normally about 98-122 m (320-400 ft) above their present level.

Below the bottom of drill hole WIPP 16, the estimated depth to the Fletcher Anhydrite is 223 m (700 ft) at Hill C. The presence of a moderately disturbed upper Rustler Formation in WIPP 16 seems to imply that there may not

have been the rapid downward movement in this pipe, but more than 183 m (600 ft) of rock of various lithologies was let down slowly, only tilting about 35° at its final resting depth. Here the two pipes differ in the condition of the rock, Hill A containing brecciated and jumbled rock down to the Fletcher Anhydrite Member, Hill C containing these only to the top of the Rustler Formation.

The dissolution front, moving from west to east, had penetrated into the Salado Formation at Hill A, but only into the Rustler Formation at Hill C at the time of collapse of the pipe, presuming that the two pipes formed at nearly the same time.

The caliche overlying Hill C has been downdropped toward the center of the pipe in several places indicating that minor collapse occurred after the main collapse. This minor collapse can be dated as less than 410,000 years ago.

Minor amounts of oil-stained core from both WIPP 16 and WIPP 31, as well as oil seeps in the MCC drifts near Hill C, were analyzed to see if an answer could be found to account for the presence of the oil (Palacas and others, 1982). Gas chromatograph and geochemical analysis indicate that the three oils are related to the oil from wells to the north of the pipes taken from the Yates Formation. The Yates overlies the Capitan reef on the backside of the reef. It is possible that oil from this formation migrated toward the area of the breccia pipes and either entered the rocks before collapse occurred or it was forcefully emplaced during collapse, being pushed stratigraphically upward by hydrostatic pressure as the water in the underlying void was forced upward by the infalling rocks. In WIPP 31, the oil stains were in rocks of Dewey Lake Red Beds, and Rustler and Salado Formations consisting of siltstone, anhydrite, and dolomite fragments and a matrix of mud, recrystallized halite, and glauberite crystals. In WIPP 16, the oil stains were in the Rustler Formation in anhydrite above the Magenta Dolomite Member and in halite below the Culebra Dolomite Member. The oil seeping into the MCC mine appears to be coming from a nearly vertical fault about 43 m (140 ft) from the edge of the breccia pipe.

## Possible Effect on WIPP Site

Numerous domes and sinks dot the landscape in the Delaware Basin. Some of these features can be shown to be remnants of near-surface dissolution or surface erosion; others are from dissolution and cavity formation in the Capitan Limestone. Known locations where deep dissolution occurs and forms structures called breccia pipes are limited to areas over the buried Capitan reef, no closer than 16 km (10 mi) to the WIPP site. The four known occurrences are Hills A, B, C, and the Wills-Weaver site.

Collapse of these structures, at least to the surface, occurred sometime before 400,000-500,000 years ago.

Locales on and around the WIPP site that were investigated for evidence of pipe formation, with none being found, include the sites of drill holes WIPP 13, WIPP 32, WIPP 33, and WIPP 34. Numerous surface features were mapped and found to be near-surface erosion and dissolution features. No examples of breccia pipes that could lead to breaching of a repository at the WIPP site have been found to date and are not likely because the Capitan Limestone is not present beneath the site.

### DRILL-STEM TESTS, WIPP 31

#### By J. W. Mercer

#### INTRODUCTION

During drilling and coring of WIPP 31 reentry, formation tests were conducted over selected intervals of the borehole to determine the possible presence of fluids (liquids or gases) and, if present, to obtain estimates of quantity, quality, and source. The formation tests were conducted using standard drill-stem test procedures as described in Dolan and others (1957), Bredehoeft (1965), Hackbarth (1978), and in "Supplement #1 to the field operations plan for WIPP 31 Re-Entry" as discussed in a letter from W. D. Weart. SNL, to D. Schueler, DOE, dated July 25, 1980.

The drill-stem test is a temporary well completion whereby the zone of interest in the borehole is isolated by the expansion of a rubber packing element or packer attached to the drill string. These packers isolate the test interval, relieving the mud column pressure and allowing the zone to produce formation fluid (if present) to the drill pipe. In addition to these packers, the drill-stem-testing tool consists of valves, pressure-recorders, and related equipment. During each individual drill-stem test, normal procedures call for multiple opening (flow-in) and closing (shut-in) of the tester valve with subsequent recording of the pressure changes. As discussed in Bredehoeft (1965), interpretation and analyses of drill-stem tests can yield information about the undisturbed formation pressure, a coefficient of permeability for the stratigraphic interval tested, and in some cases a sample of formation fluid.

#### ANALYSIS

During coring of WIPP 31, seven individual formation tests were attempted over various stratigraphic intervals in the borehole. Of these seven tests, only five were successfully completed, the first two failing because of malfunction of the testing tool. The procedure prior to each drill-stem test included running geophysical logs (gamma, density, and neutron) for lithologic control as well as a caliper to select packer seats. As drilling proceeded, the core was monitored for any fracturing or lithologic changes that might indicate a zone of fluid entry.

Field data obtained during testing are included in table 6 and various packer configurations for the tests are shown on figure 33. These tests (DST-3 and -4) indicate that the zone tested from 246 to 324 m (808 to 1064 ft, DST-3) and 246 to 376 m (808 to 1235 ft, DST-4) contained some fluid, however, production rates were so low that the only fluid recovered was diluted drilling mud. Calculated permeabilities were 0.57 and 0.90 millidarcies (mD), respectively. DST-5 from 371 to 426 m (1,216 to 1,396 ft) indicated very low permeability with a calculated value of 0.11 mD. The tests for DST-6 (456-514 m or 1,495-1,687 ft) and DST-7 (451-604 m or 1,480-1,981 ft) indicated the formation was extremely tight and did not yield enough fluid to make calculations for permeability.

Subject Oil Seeps in Salt Section P.C.A. Mine Area

From L. P. Corbin

File

Two areas in the P.C.A. Mine have oil seeps in the salt section.

The first area is in Sections 5, 8, and 9, T. 20 S., R. 30 E. as shown on Figure 1. The top of the salt in this area is approximately 490' and the bottom of the salt is about 1590'. The Main South Haulage Tunnel encountered an oil seep in the tunnel heading which is at a depth of about \$27'. Oil flowed slowly out of a drill hole in the tunnel face. The flow was killed by tamping a wooden plug into the drill hole. As shown on Figure 1, the tunnel was rerouted at considerable expense only to encounter another seep of smaller volume. Both locations are still accping oil at a very slow rate. A core test, PCA 107, shown in Section 5 on Figure 1, had seven zones of oil stained core over an interval of 304' in the salt section. These seeps are thought to be coming from an abandoned oil test "Continental Chase" which was drilled in the late 1920's in the NE-1/4 Sec. 8, T. 20 S., R. 30 E.

The second area of oil seeps is in the east end of our West Orebody (Figure 2). The top of the salt in this area is approximately 360' and the bottom of the salt is about 1041'. Here in Room 5, Breakthrough 13, as described by E. C. Jourdan, chief mine engineer "The seep was interesting in that it occurred in a fine vertical fracture within the ore horizon and extends for an unknown distance into the salt above and below the ore zone." This seep is approximately 600' below the surface and 1000' from the nearest abandoned oil well in the Getty Pool. In the National Potash Mine, about 900' south of our oil seep in Room 5, Breakthrough 13, another oil seep was encountered. This seep is about 700' from an abandoned oil well in the Getty Pool. PCA Core Test 74, in this same area, showed two zones of oil stains in the salt section at 549' and 565'4". Core Test 74 is located between two abandoned oil wells, one about 1000' due north, the other 1000' due south.

### NATIONAL POTASH COMPANY

P. O. BOX 731 CARLSBAD, NEW MEXICO

August 1, 1973

Mr. Roy H. Blackman Resident Counsel Potash Company of America P. O. Box 31 Carlsbad, New Mexico 88220

Dear Mr. Blackman:

This pertains to an incident in the spring of 1965 in which we encountered evidence of oil seepage in operations at our Eddy Mine. The location where this occurred was approximately 1,000 feet from the west line and 100 feet from the north line of the NW-1/4, Sec. 25, T. 20 S., R. 29 E. Altogether there were some three or four oil stains present, and two separate entries in the panel were affected.

The material involved at the site was horizontally bedded and consisted of 5 feet of sylvinite overlaid by 1 to 1-1/2 feet of clay. No particularly unusual physical conditions were present other than the fact that it was a salt dome area in which the seeps were encountered.

Mining operations in the area were discontinued immediately in order that the seep conditions could be investigated. This, of course, necessitated transfer of operations, including removal of all equipment by the production crews involved, to another area of the mine.

Since the nearest well was the Getty No. 1, which was approximately 700 feet from the location of the seeps, it was suspected as their source. The U. S. G. S. investigated and determined that this well had not been properly and adequately sealed. So the owner was required to reseal it in an approved manner. It is my understanding that this led further to a check of several other wells in the Getty pool in which the findings of such inadequacy were essentially the same and in which similar corrective action was also taken.

If, for any reason, additional information in regard to this matter is needed, I am sure it can readily be obtained from the U. S. G. S. office in Roswell, New Mexico, as personnel from there were involved in the incident.

Very truly yours,

Industrial Relations Manager

#### NO. 5 SHAFT PREGROUTING PROGRAM

The IMC pregrouting program at No. 5 Shaft consisted of trying to grout a 32-foot diameter curtain from the standing water table to the top of the salt which is at a depth of 295 feet. The purpose of which was to stop any inflow of water during the sinking of No. 5 Shaft.

In the first stage of the grouting program 276,420 pounds of grout was pumped from the surface to a depth of 100 feet, but tests showed that the water inflow would not be stopped.

Grouting was continued and this extended phase of the grout program used 1,727,985 pounds of grout.

At the completion of the pregrouting program, a total of 2,986,705 pounds of fly ash/cement grout and 99,100 pounds of chemical grout were used. The holes of the grout curtain were grouted to a final pressure of 150 psi. The curtain was then pump tested and found to have a low water inflow rate.

However, during the excavation of No. 5 Shaft, at a depth of 72 feet, the grout curtain failed. There was a 600 gpm inflow of water which caused the shaft to flood.

JP:d

8-6-86

The pregrouting of No. 5 Shaft was conducted from the surface with a Drill Tech D-40K drill, an Acker diamond core drill, cement grout plant, chemical grout plant and batch plant.

The first stage of the program was to drill and grout a series of 24 holes to a depth of 100 feet. The diameter of the grout ring was 32 feet. The spacing between hole centers was approximately 4.2 feet.

The upper 20 feet of ground was cased with 6 inch pipe which was grooved for victaulic type couplings. Six holes, called primary holes or 'P' holes were drilled first. The spacing between holes was approximately 16.75 feet. These 'P' holes were drilled and grouted in stages. The method used in the first six holes was to drill with air and note when water was encountered. The holes were then drilled with water to determine any loss circulation zones. When the holes encountered bad ground, the drilling was stopped and the hole grouted with a cement and fly ash mix grout. This pattern was continued to 100 feet or until the clay seam was encountered. Water in the drill holes was blown out before grouting was started. Also a water injection test was made just before grout injection. The water injection test was made by timing the rate the grout pump could inject water into the ground at a controlled pressure. Usually 7.5 gallons of water was injected. Water was ejected from the holes by placing a two inch plastic pipe, connected to the drill compressor, into the hole and forcing the water out.

The grouting of the first six holes was done as bad ground was encountered and circulation was lost. It was anticipated that cavities could be encountered, so the first six holes were evaluating the ground from the surface to the clay at 100 feet. There were no cavities found. The second set of holes to be drilled were called 'S' holes. There were six of them located halfway between the 'P' holes. These holes would leave a spacing between holes of approximately 8.4 feet. The 'S' holes were drilled and grouted in 20 foot stages from the water table at 30 feet to the clay at 105 feet. The method of grouting these holes was

#### No. 5 Shaft Pregrouting (cont'd Page 2)

to drill all six holes to the desired depth, blow out the water in the holes for 1/2 hour per hole, water test and grout each hole. No connection was observed between holes. Grout pressures were kept at or below 1 psi per foot of hole. The grout mix was altered to increase grout pressure. The mix started with 25 lbs. cement plus 25 lbs. fly ash in 50 gallons of water. After several batches of this mix, the cement and fly ash were increased to 50 lbs. each, then 75 lbs. each, then 100 lbs. each, then 125 lbs. each and finally increased to 150 lbs. each. After all holes were grouted, they were redrilled to the grouted depth plus 20 feet and grouted again.

At the completion of the 'P' holes and 'S' holes, the 'T', tertiary, holes were drilled and grouted. There were 12 'T' holes located halfway between the 'P' and 'S' holes. The final hole spacing was approximately 4.2 feet between hole centers. The 'T' holes were grouted in the same fashion as the 'S' holes.

The total grout injected in each series of holes is as follows:

| P-1        | 10,800 lbs | S-1          | 42,600 lbs |
|------------|------------|--------------|------------|
| P-2        | 6,400 lbs  | S-2          | 11,100 lbs |
| P-3        | 14,200 lbs | S-3          | 5,200 lbs  |
| P-4        | 11,400 lbs | S-4          | 10,550 lbs |
| P-5        | 8,000 lbs  | S5           | 58,700 lbs |
| <b>P-6</b> | 15,200 lbs | · <b>S–6</b> | 21,170 lbs |
| T-1        | 18,150 lbs | T-7          | 2,850 lbs  |
| T-2        | 8,800 lbs  | T-8          | 3,050 lbs  |
| T-3        | 2,800 ibs  | T-9          | 5,000 lbs  |
| T-4        | 3,000 lbs  | T-10         | 2,900 lbs  |
| T-5        | 5,500 lbs  | T-11         | 4,300 lbs  |
| T-6        | 3,150 lbs  | T-12         | 1,650 lbs  |

Total grout injected in first stage of grouting was 'P' holes – 66,000, 'S' holes – 149,320, 'T' holes – 61,150 for a total of 276,420 lbs grout.

At the completion of grouting the 'T' holes, an effort was made to core 4 holes to the salt. These holes were not completed because the ground conditions were very poor and there was excessive water present. The core recovery from the limited coring completed was very low but a few pieces of core were recovered which had large holes without cement and small

#### 'No. 5 Shaft Pregrouting (cont'd Page 3)

holes which the cement could not fill because of particle size.

Cementation West conducted a pump test in an effort to determine the water make a shaft could expect. Although the test was inconclusive, since no substantial drawdown could be obtained, Steve Phillips calculated the shaft water make at 1,250 gpm.

Since the pump test indicated excessive water was present and more grouting would be required, the decision was made to begin a chemical grout program in the upper 100 foot zone. Geoseal was purchased from Phillips Petroleum for a price of 35¢ per pound. A new series of 24 holes was described by Steve Phillips. These holes were to be located 3 feet inside the previous holes. The first 6 holes were called 'P' 100 holes.

The chemical grout program was designed to fill the very small voids in the ground which could not be reached by cement. An anticipated problem was the presence of brine water. The chemical grout would not set up in the presence of brine, therefore, the area had to be flushed with fresh water to dilute the brine. The fresh water was piped into the ground at approximately 50 gallons per minute. The holes would not fillup which indicated the ground was still very open. The geoseal was mixed and pumped into the ground. The mixing porportions were 50 lbs. geoseal in 35 gallons of water. One quart of sodium silicate solution (10% strength) was added to the mix water. The grout was pumped at a maximum pressure equal to 1 psi per foot of overburden. The early chemical grout holes had no pressure buildup and several injections were required before back pressure could be obtained. Samples of the grout were taken on every batch. The gel time was recorded. Excess foam was suppressed by spraying the surface with WD-40 solvent. The chemical grout was pumped into the holes in groups of 10 batches. There were occasions when 10 batches would not build up pressure so up to 10 more batches were injected. There also were occasions when the hole would not accept 10 batches without exceeding the maximum pressure. Therefore, less grout was injected. This process was continued from 30 feet to 105 feet in the 24 holes. From 20 feet to 30 feet, no chemical grout was used since it was above the standing water table. The chemical grout injected into the holes connected to nearby holes in some instances.

#### No. 5 Shaft Pregrouting (cont'd Page 4)

The total chemical grout injected in the zone from 30 feet to 105 feet was 99,100 lbs or 1,982 bags. The grout injected into the holes in the following amounts.

| Hole No. | lbs . of Geoseal | Sub-Total<br>Series   | Avg . Per Hole<br>lbs . of Geoseal<br>Per foot Per Hole | Avg.PerFoot<br>1 Hole |  |

Assuming grout maintains 80% of its original volume, the quantities pumped into the holes can be translated to final grout volume injected less any grout destroyed by the brine water. A 50 lb. bag of geoseal will occupy approximately 35 gallons of space or approximately 4.67 ft<sup>3</sup>. The total volume injected was 9,255 ft<sup>3</sup> of chemical grout.

A pump was conducted after the chemical grout program. The pump test indicated that a flow of 36 gallons per minute could be expected from 30 feet to 105 feet.

#### No. 5 Shaft Pregrouting (cont'd Page 5)

Two holes were cored to the salt contact which appears to be at 292 feet. These holes called C-1 and C-2 were cored with the Acker core rig. Hole No. C-1 had a 6 inch core loss just above the salt. Hole No. C-2 had a 1 foot 6 inch loss just above the salt. Hole No. C-1 lost circulation at about 250 feet. Hole No. C-2 lost circulation at 131 feet. These two holes were grouted. C-1 took 75,900 lbs. of grout and C-2 took 105,300 lbs. of grout.

The lower zone, from 105 to 295 feet was next grouted through the original holes on the 32 foot diameter circle. The holes were grouted with a cement grout. The holes were grouted at the following depths: 135 feet, 170 feet, 223 feet, 260 feet and 295 feet. Holes No. P-1, P-2, P-3, P-4, P-5 and P-6 were drilled to 135 feet. As the holes were grouted to 100 psi, they often connected with other holes. At 170 feet they also connected at 100 psi. Again at 223 feet they connected. At 260 feet stage, each hole was drilled and grouted separately. Hole No. P-6 encountered a void at 256 feet to 258 feet and lost circulation. However, the hole was grouted with 13,400 lbs. of grout. The remaining holes had no difficulties at this elevation. The stage from 260 to 295 was grouted to 260 feet with type V cement and fly ash to a grout pressure of 130 psi. The final set of 12 tertiary holes were surface cased with 5 inch casing and grouted to 260 feet with type V cement and fly ash to a grout pressure of 130 psi.

The final injection stage was made with a NaCl saturated brine and a type I or type II cement was used. No fly ash was used. The final grout pressure was 150 psi. The grout injection in the extended phase took a total of 1,727,985 lbs. of grout. The grout takes per hole were as follows.

#### No. 5 Shaft Pregrouting (cont'd Page 8)

The extended grout program was completed to the salt at 295 feet. A pump test hole was drilled to 150 feet. There were several difficulties with the pump tests, including difficulties with the probe and pump cables. However, the tests were completed in stages to the salt contact at 295 feet. The first pump test indicated low water inflow rates. A second pump test in a new test well also indicated low water inflow rates. Since the pump did not appear to be effective in the early stages of the first pump tests, the tests were conducted by using an airlift method. A 3 inch pipe and 2 - 1 inch pipes were lowered into the hole. One of the 1 inch pipes was connected to the compressor and air was forced into the three inch pipe. In this fashion all water was forced out by the escaping air flow. The second 1 inch pipe was used to place a probe into and measure the level of the water. The first pump test included measurement of the recharge rate. This recharge rate was used to calculate the permeability of the ground. A graph of the recharge rate of the zone from the top of salt to 235 feet is included. Areas above this zone were grouted prior to the pump test.

Work outside the grout curtain included grouting the ground under the raker leg and hoist foundations. These areas were grouted to a depth of 47 feet. Four holes were required for the raker leg foundations and 29 holes were required for the hoist foundations. Grout takes in these areas were: 81,700 lbs. in the raker leg foundations and 229,700 lbs. in the hoist foundations. Both areas encountered voids at 27 to 28 feet, which were filled with a cement and fly ash grout.

Additional grouting was required to fill various test holes including pump test holes and the IMC holes. Holes which were inside the grout curtain were injected with a total of 243,900 lbs. of cement fly ash grout. The IMC holes which were outside the grout curtain took 427,000 lbs. of grout. To fill one IMC hole located approximately 100 feet from the shaft required perforation since the casing could not be pulled and the hole would not accept water at 200 psi at the collar. The hole was 305 feet deep and cased with 4 inch casing. The hole was perforated from 300 feet to 260 feet on a 1 foot spacing and injected with cement. It was later perforated from 155 to 115 on a 10 foot spacing but would not accept water at 200 psi so it was only filled with cement and not grouted.

No. 5 Shaft Pregrouting (cont'd Page 9)

The total grout used in the pregrouting program was 2,986,705 lbs of cement/fly ash grout plus 99,100 lbs. of chemical grout.

The cost of the pregrout program was **and the** of which, **and and** was the cost of drilling and grouting equipment and labor. The cost of materials consumed was **and and**. The cost of miscellaneous equipment and materials including fast line, brine, brine tank, pipes and fittings, well perforation and miscellaneous labor was **and and**. The pregrout program was started on August 5, 1982, and completed on December **27**, 1982. A total of 138 days was consumed. Approximately 10,500 feet of hole was drilled.

The total material injected is equal to 32,800 bags of grout. The approximate cost per bag in place is (32,800 bags or (32,800 bags) bag. Of this cost, equipment and labor represented (32,800 materials represented (32,800), miscellaneous supplies and equipment represented (32,800) per bag.
