

# VACUUM GLORIETA EAST UNIT

## UNITIZATION AND WATERFLOOD DEVELOPMENT PLAN

VACUUM GLORIETA POOL  
LEA COUNTY, NEW MEXICO

BEFORE EXAMINER CATANACH  
OIL CONSERVATION DIVISION  
PHILLIPS PETROLEUM COMPANY  
EXHIBIT NO. 6  
CASE NO. 10485 AND 10486

MARCH, 1993

## **INTRODUCTION**

The Vacuum Glorieta Pool was discovered on January 9, 1963 with the completion of the Texaco, New Mexico "O" State well No. 12 located in Section 36, T-17-S, R-34-E of Lea County, New Mexico. The New Mexico Oil Conservation Commission defined the Vacuum Glorieta Pool to start at the top of the Glorieta formation and end at the top of the Blinbry formation. The type log from the Mobil Bridges State Well No. 95 is provided in **figure 1** with the designated formation tops and depths. The Vacuum Glorieta Geologic Sub-committee further defined the interval into Upper and Lower Paddock formations which are also shown on the type log.

The Working Interest Owners of the Vacuum Glorieta Pool formed an Engineering and Geological Technical Committee to characterize the Glorieta Pool. On February 12, 1991, the Working Interest Owners approved the Technical Committee's Report dated November 1990. On this same date, the Working Interest Owner's agreed to divide the Pool into two EOR study areas because of distinct reservoir and geologic characteristics found between the east and west portions of the pool. A map showing the Vacuum Glorieta West Unit and the Proposed Vacuum Glorieta East unit is shown in **figure 2**.

The proposed Vacuum Glorieta East Unit encompasses 4,240 surface acres in parts of T-17-S and T-18-S of R-35-E in Lea County, New Mexico. A base map of the proposed unit boundary is shown in **figure 3**. The proposed unit contains 94 current Glorieta completions and as of January 1, 1992, has produced 43.4 MMBO. The 1991 production averaged 60,330 BOPM or 1978 BOPD. A plot of historical oil, gas, and water production is provided in **figure 4**.

The proposed unitized interval is from the top of the Glorieta to the top of the Blinbry or approximately 5800 feet to 6200 feet as shown on the type log (**figure 1**). The Upper Paddock is the dominate pay within this interval. It is present over the entire proposed unit area and is approximately 100 feet below the top of the Glorieta. The lower Paddock is present in only the extreme south west portion of the unit and is not targeted for EOR development in the VGEU.

Below is table that lists the reservoir properties and fluid characteristics for the proposed VGEU as determined from the November 1990 Engineering-Geological Technical Committee Report.

|   |          |
|---|----------|
| Surface Area, Acres . . . . .                 | 4,240    |
| Depth, feet . . . . .                         | 5,800    |
| Formation Type . . . . .                      | Dolomite |

| Original Oil in Place, MSTBO . . . . .        | 107,296  |

## **RESERVOIR DEVELOPMENT PLAN**

### **WATERFLOOD DEVELOPMENT:**

The Vacuum Glorieta East Unit waterflood development will occur in four stages starting in fourth quarter of 1993 and ending in 1996. Development will include drilling a total of 41 new wells, conversion of 15 existing wells to water injection, and the reactivation of 9 shut-in producers. The waterflood development plan is provided in a plat format in figure 5 and in a tabular format in table 1. A detailed summary of the unit waterflood development schedule is discussed in a following section labeled "Development/Investment Schedule".

Approximately 70% of the Vacuum Glorieta East Unit will come under waterflood. This development is consistent with the two distinct depletion mechanisms influencing the Vacuum Glorieta Pool. The east and south flanks of the pool have been influenced by water encroachment, while the central and western portions of the field have been depleted by solution gas drive. This is evident by the widely varying GOR, water cut and recovery efficiencies experienced in wells across the field. Waterflood development will begin in the northwest portion of the unit where oil rates are typically low and progress toward the central portion where many wells are producing at top allowable and near top allowable rates. The south and east flanks of the unit will be held for future CO<sub>2</sub> flood development.

The waterflood will be developed on a 40 acre five spot pattern. The unit is currently drilled on 40 acre proration units. Therefore, 31 twenty acre infill injection wells will be drilled to complete the waterflood pattern. This includes six lease line injectors to be drilled on the VGEU-VGWU border. New injectors are preferable to existing well conversions. The new injection wells will have superior wellbore integrity, which will ensure that injection fluid remains in zone making the flood more efficient. Four replacement wells will also be drilled. They will replace wells that have been plugged and abandoned or have production casing less than 4 1/2" diameter.

Six infill producing wells will be drilled and cored in fourth quarter of 1993. They are located in areas where acceleration of primary reserves is economic and will provide a boost to cash flow. Additionally, they are located across the field and should represent a good cross section of geologic and petrophysical environments in the Vacuum Glorieta Pool. The core analysis will be used to modify the waterflood model, improve waterflood response, and plan CO<sub>2</sub> development. These six wells will be converted to water injection wells in late 1996. A detail of the core analysis is provided in a following section.

All newly drilled wells will be completed with 5 1/2" casing set at the base of the Paddock and cemented to the surface. Typically, 8 5/8" surface casing will be set in the rustler anhydrite just above the Salado salt section and cemented to surface. However, in areas where waterflow from the Salado salt section exists, an additional string of intermediate casing will be set and cemented to surface. This is anticipated in only three wells. All well completion diagrams are detailed in figures 15 to 19.

## **CO2 FLOOD DEVELOPMENT:**

Field wide CO2 injection is anticipated to start in 1998. By 1998, two important events will have occurred. One is that significant VGEU waterflood response data and core analysis data will have been gathered and analyzed. The second is that the waterflood portion of the field will have reached the CO2 miscibility pressure of 1426 psi. CO2 flood development will require drilling 9 infill injection wells, drilling 6 replacement wells, converting 3 producers to injection, and reactivating 6 producers. See figure 6 for proposed CO2 development plat. Pressured CO2 could be purchased from the East Vacuum Grayburg San Andres Unit and distributed through the EVGSAU CO2 distribution system. Most of this system will be utilized. However some new injection line and all new injection wellheads will be required. CO2 contaminated gas and gas liquids may be sent to the East Vacuum Liquids Recovery Plant for liquid extraction and CO2 processing. The CO2 flood development will be a stand alone project. Its development will require a detailed technical study and separate development plan. A Unit Technical Committee will be formed in 1996 to study CO2 flood development and make recommendations to the Working Interest Owners by mid 1997.

## **DISCRETIONARY WELL DEVELOPMENT:**

The east half of section 31 and part of section 5 will not be under any planned development initially. This area is characterized as having low cumulative oil recovery and low producing rates. Based on current geological and reservoir data, this area appears to have marginal waterflood potential. Fortunately, this area will be flanked with water injectors on the north, east and west sides. The producing wells in this discretionary area will be monitored as the waterflood progresses. If the wells close to the water injectors respond favorably, a plan to develop this acreage will be proposed to the Working Interest Owners. This may involve drilling 11 infill wells, drilling 8 replacement wells, and reactivating 10 producers. See figure 7 for discretionary well development plat. Development of the discretionary area will be a stand alone project contingent on Working Interest Owner approval.

## **RESERVOIR MODEL SIMULATION**

A full field, fully implicit, three dimensional model was developed to study and to evaluate the various producing mechanisms in the east half of the Vacuum Glorieta Pool. This model provided a basis for describing the depletion mechanism as well as predicting waterflood and CO<sub>2</sub> flood potential. The model was constructed with a 95 X 55 X 3 grid covering the entire proposed Vacuum Glorieta East Unit area. The model components were based upon geological data presented in the November 1990 "Vacuum Glorieta Engineering - Geological Technical Committee Report.

Model components were adjusted to roughly match cumulative oil production on a well by well basis, but primary emphasis was placed on overall field performance. Particular interest was given to matching the overall oil rate decline, GOR trends, and water cut. The model was not designed to study detailed response on a well by well basis, but to study the overall field depletion and EOR response.

The reservoir model was run in prediction mode throughout the history matching phase. Key elements which were adjusted to provide a sufficient history match include the strength of the water influx mechanism and the volume of original oil in place. A strong aquifer was added to the northeast, east, and southeast flanks of the unit boundary. This was required to match the slowly increasing water cuts, declining GOR trend, and favorable oil decline rate experienced in the eastern portion of the pool. Water influx alone was not sufficient to match the overall reservoir performance. The volumetric oil in place was adjusted upwards to match the cumulative oil production and obtain a suitable history match. Plots of the oil, GOR, and water cut history matches are provided in figure 8.

This model was used to generate waterflood forecasts based on the history match.

## **WATERFLOOD FORECAST**

Three injection patterns were considered: a 160 acre inverted 9 spot, an 80 acre five spot, and a 40 acre five spot which involved drilling one additional injector per pattern. The 40 acre five spot was chosen as the best pattern because the 20 acre infill injectors increased inter-well connectivity, improved overall sweep efficiency, and maximized oil recovery. The 40 acre five spot pattern was introduced into the reservoir model and used as the basis for all of the waterflood prediction cases.

Waterflood reserves were forecast using risk analysis of several model predictions in which certain debatable waterflood parameters were varied. These parameters are the reservoir volume, the strength of the aquifer on the east half of the field, and the water injection rate. A total of twelve waterflood sensitivity forecasts were generated. A base case reservoir volume was developed from the model history match. This volume was reduced 27 % to create a low reservoir volume case. On each of these two cases the strength of the aquifer was varied from strong to moderate to non-existent during the waterflood phase generating six distinct forecasts. A further sensitivity was run on each of these cases by limiting the maximum water injection rate to 500 bpd/well and to 750 bpd/well. The parameter variations are illustrated on a decision tree provided in **figure 9**. One additional sensitivity case was run in which the initial water saturation was raised from 27 % to 37 %. This lowered the ultimate recovery by 25 %, but increased waterflood response time. The over all effect on project economics was minimal.

A most probable waterflood response was generated from the twelve waterflood sensitivity cases. Each of the waterflood parameters (reservoir volume, aquifer strength, and injectivity) was assigned a percentage reflective of its probability of occurrence. The most probable waterflood forecast was generated by weight averaging the annual oil volume from each of the twelve waterflood predictions based on these probabilities. The probability factors of each parameter and the weighted average formula are provided in **figure 10**. The most probable waterflood response forecast is illustrated in tabular form in **table 2** and graphically in **figures 11 and 12**. The forecasted oil rate peaks in 1999 at 4987 BOPD and accumulates 20,530,141 BO (including primary oil) over the 27 year life of the project. This is the waterflood response that should be used to calculate waterflood economics.

## **CORE ANALYSIS PROGRAM**

### **INTRODUCTION:**

The 1993 development plan for the Vacuum Glorieta East Unit consists of drilling six infill producers. The six infill wells will be cored through the unitized interval with total cored footage ranging from 1500 to 1800 feet. The objective of the coring program is to provide the detailed reservoir characterization necessary to fully understand the complex geology and reservoir heterogeneities of the Glorieta and Paddock formations in the Unit area. Detailed reservoir characterization will be accomplished using the new core analysis data described below as well as data from previous studies of the ten cores taken by Exxon, Shell, Mobil, Texaco, and Phillips. The routine and special core analysis data gathered on the new cores will assist in waterflood management and CO<sub>2</sub> flood design.

### **METHODS:**

Core analysis methods will consist of the following: routine core analysis, special core analysis for geological properties, and additional special core analysis for reservoir properties. Routine core analysis and geologic special core analysis will be performed on all six new cores. Special core analysis for reservoir properties will be conducted on representative samples of the primary flow units taken from two native state cores that best depict the reservoir intervals contributing to waterflood response. The two native state cores will be chosen from the six well coring package.

### **ROUTINE CORE ANALYSIS:**

The routine core analysis will consist of whole core modified Dean Stark analysis and will include Boyle's law porosity, grain density, residual water saturation, residual oil saturation, as well as maximum and 90 degree permeability. In addition, the data will be presented in tabular and graphic format. Special core analysis samples will be identified and removed from the intervals that best represent the primary flow units. If necessary, additional samples will be preserved for future special core analysis. The remaining core will be slabbled. The core photography protocol will consist of whole core photographs under ultraviolet light and slabbled core photographs in daylight.

## **SPECIAL CORE ANALYSIS (GEOLOGIC CHARACTERIZATION):**

The special core analysis for geologic characterization will include identification of lithofacies types, determination of depositional environments, and delineation of significant diagenetic events from core description and petrographic analysis. Petrographic analysis will include thin section description and scanning electron microscopy with EDS. In addition, porosity types, pore sizes, and pore geometry will be identified and described using thin sections, SEM, and pore casts. Pore geometry characterization will include the determination of aspect ratio (pore size/pore throat size), pore size distribution, coordination number (number of pore throats per pore), and porosity distribution (layered, random, etc.).

The primary objective of this detailed geological work is to validate and further define the four major facies types found in the unitized interval and to tie these facies to the primary flow units. The primary flow units will be defined by porosity and permeability relationships and distinguished by lithologic character and log signature.

The major facies types present are: quartz sandstone, pelletal mudstone, skeletal packstone-wackestone, and oolitic-pelletoidal grainstone. The three carbonate facies types exist as limestone or dolomite depending on their location in the unit. In general, the carbonate facies are dolomitized in the northern half of the unit while occurring primarily as limestones in the southern half of the unit. The special geologic core analysis will better define the diagenetic events controlling the distribution of carbonate lithologies throughout the unit. Furthermore, this analysis will also provide predictive rock type (lithofacies) models to further elucidate the porosity-permeability relationships found in the core data.

## **SPECIAL CORE ANALYSIS (RESERVOIR PROPERTIES):**

Special core analysis for reservoir properties will include Amott's wettability, capillary pressure, relative permeability, confining stress porosity, confining stress permeability and CO<sub>2</sub>-reservoir fluid compatibility. The CO<sub>2</sub>-reservoir fluid compatibility tests will be performed selectively on primary flow unit samples from the two native state cores. The following list describes the special core analysis techniques and respective parameters to be determined: 1) Amott wettability and end point relative permeability ( $K_{ro} @ S_{wi}$  and  $K_{rw} @ S_{ro}$ ), 2) Formation resistivity factor and cementation exponent at confining pressure, 3) Formation resistivity index and saturation exponent at confining pressure, 4) Mercury injection - capillary pressure and pore size distribution up to 2000 psia. 5) Air-brine capillary pressure up to 70 psi, 6) Confining pressure gas permeability, 7) Pore volume compressibility, 8) Steady state water-oil relative permeability, 9) Unsteady state water-oil and gas-oil relative permeability, and 10) Carbon dioxide core flood and residual oil saturation to CO<sub>2</sub>.

## **PRODUCTION AND INJECTION FACILITIES**

### **PRODUCTION FACILITIES:**

All produced oil, gas, and water will be gathered into two tank battery facilities. The west tank battery will be located in Section 31 at the present Shell site, and the east tank battery will be located in Section 27 at the present Phillips site. See figure 13. All existing Shell and Phillips tankage and equipment will be phased out and replaced with new equipment.

Each new tank battery will have a 10' X 28' production treater that is anticipated to eliminate the need for a free water knockout. Each battery will have one 500 barrel oil sales tank, a 1000 barrel oil divert tank, and a 2000 barrel oil overflow tank. All the oil tanks will be constructed of coated steel. A vapor recovery unit will be installed on the oil tanks and will discharge tank vapors to the gas sales line. Water from the production treater will first go to a 2000 barrel skim tank and then to a 2000 barrel suction tank where it will be pumped to the East Vacuum Grayburg San Andres Unit central tank battery for treatment and re-injection. A 2000 barrel water overflow tank is also provided for emergency use. All water tanks will be constructed of fiberglass. All tankage will be equipped with automatic gauging and alarms. Each tank will be set on a leak detection foundation made of Drisco lined concrete. Any leaking fluid will flow to the perimeter of the tank and be visible. There will be four test treaters located at each battery. Each test treater will be dedicated to a separate test header and have a 500 barrel oil test tank to ensure more accurate oil tests. Both batteries will be equipped with night time lighting for personnel safety and site security. A detailed schematic of the tank battery layout is provided in figure 14.

### **PRODUCING WELLS AND FLOWLINES:**

All newly drilled producing wells will be completed with 5 1/2" casing per the attached figure 15. All new producers will be equipped with Lufkin beam pumping units and electric motors or submersible pumps as conditions warrant. The producing wells will be connected to either the east or west tank battery per figure 13. Wells anticipated to produce less than 150 BFPD will have 2" flowlines. Those anticipated to produce over 150 BFPD will be equipped with 3" flow lines. All flowlines will be constructed of SDR-7 Marlex line pipe converting to steel linepipe 100' from the tank battery. All flow lines will be equipped with high pressure shut downs. These are located at the wellhead and shut down the lift equipment to protect the marlex flowline from high pressure. Existing steel flowlines will be phased out and abandoned within the first two years.

## **WATER SUPPLY AND INJECTION SYSTEM:**

The maximum expected water injection rate is 31,000 BWPD. This will occur in 1997 when the full waterflood area is developed, and much of the reservoir is undergoing fill-up. Injection rate will slowly wane and stabilize at about 24,000 BWPD. See table 3 for water injection and water production forecast.

Subject to EVGSAU Working Interest Owner approval, the Vacuum Glorieta East Unit will purchase pressured water from the EVGSAU which overlays much of the VGEU area. The EVGSAU water distribution system will be utilized wherever feasible. However, additional injection lines will be installed as required see figure 20. New injection lines will be buried 2 1/2" 2000 psi fiberglass. The EVGSAU water injection system has the 31,000 BWPD spare pump capacity and can deliver water to both units sufficiently at 1300 psi wellhead pressure. EVGSAU will be mixing produced water from the Paddock, Glorieta and San Andres, as well a fresh water make-up to supply injection water to both units. Water compatibility tests were run which indicate that mixing these waters will produce some precipitates, mainly calcium sulfate. This scaling tendency is reduced by dilution with the fresh water. However, the injection water will be chemically treated to protect the injection facilities and wells.

## **WATER INJECTION WELLS:**

All newly drilled injection wells will be completed with 5 1/2" casing per the attached figures 16 and 17. Each injector is designed to inject a minimum of 750 BWPD. They will be equipped with internally plastic coated 8RD tubing and a nickel coated Baker A-3 Lok-Set packer. The surface wellhead and injection assembly is designed for 2000 psi service and will include a master valve, flow tee, check valve, strainer, manual choke, and turbine meter. See figure 21 for injection assembly detail.

## **FLUID METERING:**

Daily fluid production will be metered at each of the two tank batteries. Oil will be metered through a LACT unit into the oil sales line. Water will be metered through a Halliburton flow meter located between the production treater and water storage tank. Gas will be measured by the Gas Purchaser utilizing a orifice plate meter run and flow totalizer. Individual well tests will be run at each of the four testing facilities located at each of the two tank batteries. Oil, gas and water will be separated at the test heater treater and measured separately. Oil test rate will be metered through a Halliburton flow meter in conjunction with a 500 barrel test tank for more accurate oil test results. Water rate will be measured with a Halliburton flow meter. Gas rate will be measured through an orifice plate meter run and Barton differential meter. The well test facilities are designed to test producing wells within the waterflood area every two to three weeks and to test wells outside the waterflood area quarterly. A producing fluid level will be recorded with every well test. Injection water rate will be metered at each wellhead using a Halliburton turbine meter. Pressure will be measured with a calibrated liquid filled gauge. Injection well rate and pressure will be recorded weekly and reported monthly.

## **AUTOMATION AND SYSTEM ALARMS:**

Pump off controllers will be installed on all producing wells within the waterflood area, and on wells outside the waterflood area that produce over 10 BOPD. The pump off controllers will monitor well performance and control pumping time to optimize oil production. Each POC will be coupled with a Remote Telemetry Unit that will transmit down time statistics to the Vacuum Field operations office located in Buckeye, NM. The injection system and wells will be controlled manually using the Halliburton meter and choke at the wellhead. If warranted, injection well Supervisory Control and Data Acquisition automation equipment may be installed in the future as a stand alone project.

A wide array of alarms will be installed at each of the two tank batteries. High level alarms will be installed on the water overflow tank, water suction tank, 500 bbl oil sales tank, and oil divert tank. The production treater and test treaters will have high level alarms, oil in water alarms, water in oil alarms, and high pressure alarms. All tanks will have automatic gauging systems. The LACT and vapor recovery units will each have shut down alarms, and the instrument air system will have a low pressure alarm.

## **DEVELOPMENT/INVESTMENT SCHEDULE**

Development of the proposed VGEU will occur over a four year period described below and shown graphically on **figure 22**. The following schedule is based on a VGEU unitization date of September 1, 1993.

### **YEAR 1993:**

Year 1 will include preliminary tank battery construction at the new VGEU East and West tank battery locations. Phase out of existing tank batteries will begin with the elimination of six locations. Six new infill producers will be drilled, cored, completed, and tied into the appropriate tank battery.

### **YEAR 1994:**

Year 2 will complete the construction of the East and West tank batteries and tank battery automation. The twelve remaining tank batteries will be eliminated, and all existing wells will be tied into the new batteries. Installation and connection of the VGEU produced water lines to the EVGSAU injection system will be complete. Installation and connection of water injection lines to the EVGSAU system will begin with the connection of fifteen VGEU injection wells. Installation of producing well automation will begin. Four shut-in producers will be reactivated, and fifteen new injection wells will be drilled and completed (ten infill, two replacement, and three lease line wells). Water injection will begin by mid-year.

### **YEAR 1995:**

In year 3, four wells will be converted from producers to water injection. Thirteen new water injectors will be drilled and completed (ten infill and three lease line) for a total of seventeen additional injection well tie-ins to the EVGSAU water injection system. One replacement producer will be drilled and completed.

#### **YEAR 1996:**

In year 4, eleven wells will be converted to water injection. Five new infill injection wells will be drilled and completed for a total of sixteen additional tie-ins to the EVGSAU water injection system. This completes the VGEU/EVGSAU injection system tie-ins, at a total of 48. In addition, four shut-in producers will be reactivated, and one replacement producer will be drilled, completed and equipped. Increased lift equipment will be installed on five producing wells. VGEU waterflood development will be essentially complete by year end 1996.

#### **YEARS 1997 - 2007:**

Increased lift equipment will be installed on an additional fifty-six producing wells over this time period. A year by year break down of increased lift equipment is tabulated in table 4.

#### **ANNUAL CAPITAL EXPENDITURES:**

The annual capital expenditures for the above development schedule are summarized below. All dollar amounts are in 1993 M\$.

| <u>Year</u> | <u>Tangibles</u> | <u>Intangibles</u> | <u>Totals</u>   |
|-------------|------------------|--------------------|-----------------|
| 1993        | \$ 1,016         | \$ 2,034           | \$ 3,050        |
| 1994        | \$ 3,903         | \$ 4,413           | \$ 8,316        |
| 1995        | \$ 1,680         | \$ 3,535           | \$ 5,215        |
| 1996        | \$ 1,552         | \$ 2,152           | \$ 3,704        |
| 1997-2001   | <u>\$ 4,063</u>  | <u>\$ 587</u>      | <u>\$ 4,650</u> |
| Total       | \$12,214         | \$12,721           | \$24,935        |

A detailed investment schedule is provided in table 5, and a summary of the drilling cost estimates is provided in table 6.

## **OPERATING COSTS**

### **WELL OPERATING COSTS:**

Annual operating cost projections are shown in detail in table 7. The Premises used for the operating costs are outlined below.

| <u>Well Operations:</u> | <u>Annual cost per well<br/>(\$ M 1993)</u> |
|-------------------------|---|
| Primary Producer        | \$ 18.0                                     |
| Waterflood Producer     | \$ 30.0                                     |
| Injection well          | \$ 10.0                                     |

### **PURCHASED INJECTION WATER:**

The treatment, pressuring, and transportation of produced water and water make-up for the VGEU waterflood will be supplied by the East Vacuum Grayburg San Andres Unit. This service is estimated to cost \$ 0.09 per barrel of water injected. This price is contingent on EVGSAU Working Interest Owner approval.
