February 24, 1982

Division Director  
New Mexico Oil Conservation Commission  
State Land Office Building  
Santa Fe, NM 87501

Dear Sir:

Petro-Lewis Corporation requests administrative approval for downhole commingling in its L. G. Warlick #1. We wish to commingle oil produced from Blinebry perforations at 5585' - 5737' and Penrose Skelly Grayburg perforations at 3736' - 3839'.

As shown on the attached well bore schematic the two zones are now separated by a packer. We are pumping the Blinebry zone below the packer and the Penrose Skelly is not producing. The last production date for the Penrose Skelly was November 1979. It was uneconomical to continue pumping that zone for 1 BOPD, so it was shut in.

If granted approval of this application, we intend to remove the packer and pump both zones through a single string of tubing. This will improve pumping efficiency as well as allowing recovery of reserves from the very marginal Penrose Skelly Graybrug zone which by itself is uneconomical to produce.

The information required by Rule 303-C is attached. We have notified all offset operators by copy of this application. Insofar as we have complied with the requirements of Rule 303-C we respectfully request your approval. ✓

Sincerely,

*Michael G. Handren*

RE: Application for  
Downhole Commingling  
L. G. Warlick #1

Dear Sir:

In accordance with Statewide Rule 303-C, I am submitting the following information in application for a downhole commingling permit.

- a) Operator: Petro-Lewis Corporation  
P. O. Box 2250  
Denver, CO 80201
- b) Lease & Well: L. G. Warlick Lease  
Well Number 1  
Unit A, Sec. 19, T 21 S, R37E  
Lea County, NM
- c) Completed Pools: Blinebry - Perfs @5585' - 5737'  
Penrose Skelly Grayburg - Perfs @3736' - 3859'  
This dual completion was authorized by order  
MC-1599 on February 18, 1965.
- d) Current Production Test on from C-116.  
A current test (within 30 days) is attached for the Blinebry zone. We do not have a current test (within 30 days) for the Penrose Skelly zone since that zone has not produced since November 1979. The last producing rate at that time was 1.6 BOPD, 10 BWPD, 60 MCFGPD on pump. This test is attached on from C-116.
- e) A Production Decline Curve for each zone is attached.
- f) Estimated Bottom Hole Pressure for each atrifically lifted zone.  
Blinebry - ~~250~~ psi **855**  
Penrose Skelly Grayburg - ~~150~~ psi **878**

*Please show  
how these pressures  
were determined  
Thank you  
Michael  
Stogner*

Application for Downhole  
Commingling-L. G. Warlick #1  
February 24, 1982  
Page 2

- g) A Description of the Fluid Characteristics:  
Blinebry Oil - 34.4° API gravity, sour crude  
Penrose Skelly Oil - 37.5° API gravity, sour crude
- h) The value of the crude will not be reduced. These same zones are commingled downhole in other wells and also in surface facilities on Petro-Lewis' Warlick, Warlick A, Warlick B, and State DC Leases.
- i) All offset operators have been notified by certified mail of the proposed commingling. Copies of the receipts are attached.
- j) The ownership of both zones is common as to working interest, royalties, and overrides.

Sincerely,

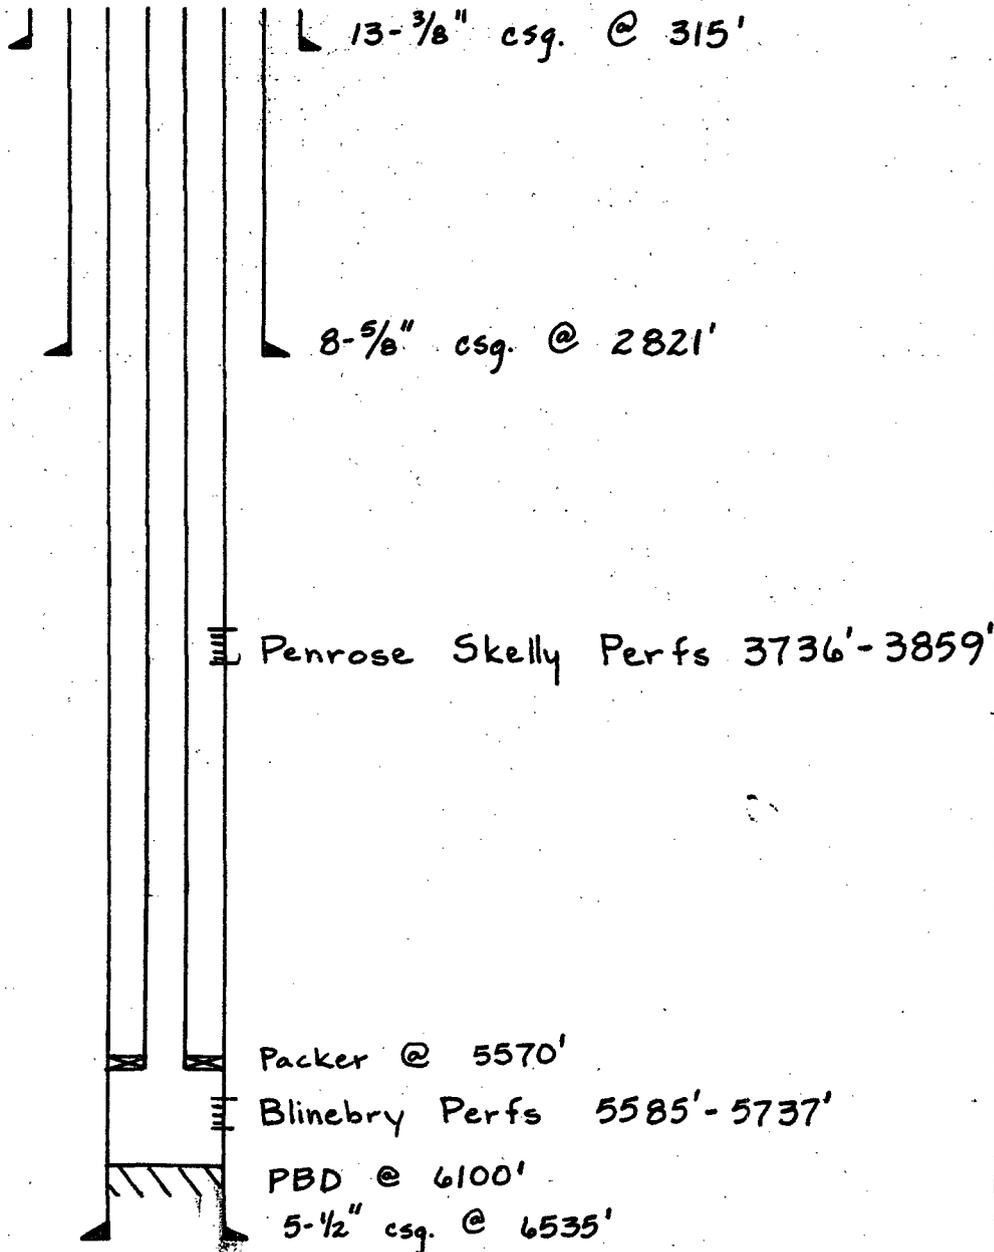

*Michael G. Handren*

GAS-OIL RATIO TESTS

Operator: Petro-Lewis Corporation  
Address: P. O. Box 2250, Denver, CO 80201  
Pool: Blinberry  
County: Lea

LEASE NAME	WELL NO.	LOCATION				DATE OF TEST	TYPE OF TEST - (X)	CHOKE SIZE	TBG. PRESS.	DAILY ALLOWABLE	LENGTH OF TEST HOURS	PROD. DURING TEST				GAS - OIL RATIO CU.FT./BBL.
		U	S	T	R							WATER BBL.S.	GRAV. OIL BBL.S.	OIL BBL.S.	GAS M.C.F.	
L. G. Warlick	1	A	19	21S	37E	1-30-82	P	None	25	10	24	15	34.4	4	8.3	2075

No well will be assigned an allowable greater than the amount of oil produced on the official test.  
During gas-oil ratio test, each well shall be produced at a rate not exceeding the top unit allowable for the pool in which well is located by more than 25 percent. Operator is encouraged to take advantage of this 25 percent tolerance in order that well can be assigned increased allowable when authorized by the Division.  
Gas volumes must be reported in MCF measured at a pressure base of 15.025 psia and a temperature of 60° F. Specific gravity base will be 0.60.

Report casing pressure in lieu of tubing pressure for any well producing through casing.  
Mail original and one copy of this report to the district office of the New Mexico Oil Conservation Division in accordance with Rule 301 and appropriate pool rules.

I hereby certify that the above information is true and complete to the best of my knowledge and belief.

Gentlemen:

Petro-Lewis Corporation has filed an application for permission to commingle production downhole in their L. G. Warlick A well No. 1. They propose to commingle oil produced from the Drinkard and Penrose Shelly Grayburg formations.

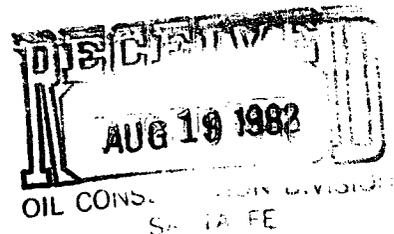

As an offset operator, Amoco Production Company has no objection to Petro-Lewis' application to downhole commingle production through the subject well.

Yours very truly,

RE: L.G. Warlick #1  
Lea County, NM

Dear Mr. Stagner:

You wish to know how I estimated the BHP of the two zones in the L.G. Warlick #1 in Lea County, New Mexico. These values were estimated from BHPs in other wells. However, after further consideration prompted by your question, I feel the pressures reported in the commingling application were wrong.

I have calculated approximate BHPs for each zone based on instantaneous shut in pressures after a recent acid job which was done on December 3, 1981. The new calculated BHP for the Blinebry zone is 855 psi and for the Penrose-Skelly Grayburg is 878 psi. These were calculated using equations from SPE Monograph 6, Acidizing Fundamentals. The calculations are attached.

In addition to the BHP information, I am also attaching copies of signed waivers from all offset operators.

I hope this information will be sufficient.

Sincerely,

Michael G. Handren  
Sr. Staff Engineer

MGH/ag

att.

Calculation of BHP from ISIP

Equation 7.1 from SPE Monograph 6

$$g_f = \frac{\text{ISIP} + \text{HH}}{\text{depth}}$$

Equation 7.2 from SPE Monograph 6

$$g_f = \alpha + (g_o - \alpha) \left( \frac{\text{Reservoir Pressure}}{\text{depth}} \right)$$

$g_o$  = overburden gradient

$g_f$  = fracture gradient

$\alpha$  = constant (.33 to .5)

HH = hydrostatic head

ISIP = instantaneous shut in pressure

for these calculations:

$$\alpha = .4$$
$$g_o = 1$$

Blinebry Zone

ISIP = 300 psig  
HH = (.4334)(5700) = 2470 psi  
depth = 5700 ft.  
 $\alpha$  = .4  
 $g_o$  = 1

substituting into Eq. 7.1:

$$g_f = \frac{300 \text{ psi} + 2470 \text{ psi}}{5700 \text{ ft.}} = .49 \text{ psi/ft.}$$

substituting into Eq. 7.2:

$$.49 = .4 + (1 - .4) \left( \frac{\text{Reservoir Pressure}}{5700} \right)$$
$$.09 = (.6) \frac{\text{Reservoir Pressure}}{5700}$$

855 psi = Reservoir Pressure

Penrose-Skelly Grayburg Zone

$$\begin{aligned} \text{ISIP} &= 400 \text{ psig} \\ \text{HH} &= (.4334) (3800) = 1647 \text{ psi} \\ \text{depth} &= 3800 \text{ ft.} \\ \alpha &= .4 \\ g_o &= 1 \end{aligned}$$

Eq. 7.1:

$$g_f = \frac{400 + 1647}{3800} = .54 \text{ psi/ft.}$$

Eq. 7.2:

$$.54 = .4 (1 - .4) \left( \frac{\text{Reservoir Pressure}}{3800} \right)$$

$$.14 = \frac{(.6) \text{ Reservoir Pressure}}{3800}$$

$$\underline{\underline{878 = \text{Reservoir Pressure}}}$$

determined relative permeability curves, when available. When relative permeability data are not available, a rule of thumb we often use is to divide the absolute permeability by 1.5 for oil-based fracturing fluids and by 5 for water-based fracturing fluids.

*Formation Porosity*

Use the average porosity of the reservoir determined from log or core analysis; porosity normally is not a critical parameter in treatment design.

*Formation Depth*

Use the distance from ground level to the middle of the formation, expressed in feet.

*Formation Fracturing Gradient*

Use the pressure, expressed as the gradient (psi per foot of depth), required to hold open the fracture just as the fracture walls are about to close. This is not the pressure required to initiate a fracture, often called the breakdown pressure. The breakdown pressure will normally exceed the fracture propagation pressure as measured by the fracturing gradient defined below.

The fracture gradient is estimated by adding the surface pressure observed instantaneously after shut-in of the fracturing pumps to the hydrostatic head of the fluid in the wellbore, and dividing by formation depth.

$$g_f = \frac{\text{instantaneous shut-in pressure} + \text{hydrostatic head}}{\text{depth}} \quad (7.1)$$

The fracture gradient for a reservoir is not constant, but changes as reservoir pressure is changed. Two example surface-pressure records for fracture treatments in the same reservoir are presented in Fig. 7.4 to illustrate this effect. The first treatment was in a newly developed field with an initial reservoir pressure of 2,000 psi; the fracture gradient was 0.7 psi/ft. At the time of the second treatment, reservoir pressure had been depleted to 1,000 psi; the fracture gradient was 0.6 psi/ft. From this example, it is apparent that a method is needed to predict changes in fracture gradient with reservoir pressure, to estimate the fracture gradient for deep, high-pressure reservoirs, and to predict the gradient for newly developed fields.

A simple, approximate method that can be used to estimate the fracture gradient is to assume it is proportional to the overburden and reservoir pressure gradients:

$$g_f = \alpha + (\text{overburden gradient} - \alpha) \frac{\text{reservoir pressure}}{\text{depth}} \quad (7.2)$$

where  $\alpha$  = constant (0.33 to 0.5) and the overburden gradient is about 1.0 psi/ft at depths less than 10,000 ft and 1.0 to 1.2 psi/ft at depths greater than 10,000 ft. To extrapolate to a reduced reservoir pressure from a fracture gradient obtained at initial reservoir pressure, substitute the old fracture gradient and reservoir pressure into Eq. 7.2 and calculate  $\alpha$ . Then, for the new reservoir pressure and the computed value of  $\alpha$ , estimate the revised fracturing gradient. More rigorous

theories for predicting the fracture gradient as a function of changes in overburden stress, pore pressure, rock tensile strength, etc. exist. We seldom have sufficient data to use these theories, however, and the simple relationship given in Eq. 7.2, although not exact, is usually adequate.

In a new field, the fracture gradient can be approximated using Eq. 7.2 with  $\alpha = 0.5$ . Remember, this is an approximate equation and that the proper value of  $\alpha$  should be verified from field data.

*Poisson's Ratio*

The fracture geometry predicted for a given formation will vary only slightly as Poisson's ratio for the rock varies. Therefore, it is sufficient to select values for Poisson's ratio based upon the general rock type. Typical values are listed below.

Rock Type	Poisson's Ratio
Hard carbonate	0.25
Medium-hard carbonate	0.27
Soft carbonate	0.30

*Mean Sonic Travel Time*

The mean sonic travel time can be used to calculate the modulus of elasticity of the formation (Young's modulus). It is best to use travel times from sonic logs taken in the well to be treated. Since Young's modulus, which is an important parameter in the prediction of fracture geometry, is normally evaluated from the sonic travel time, the travel time must be measured as accurately as possible. If in doubt, select the

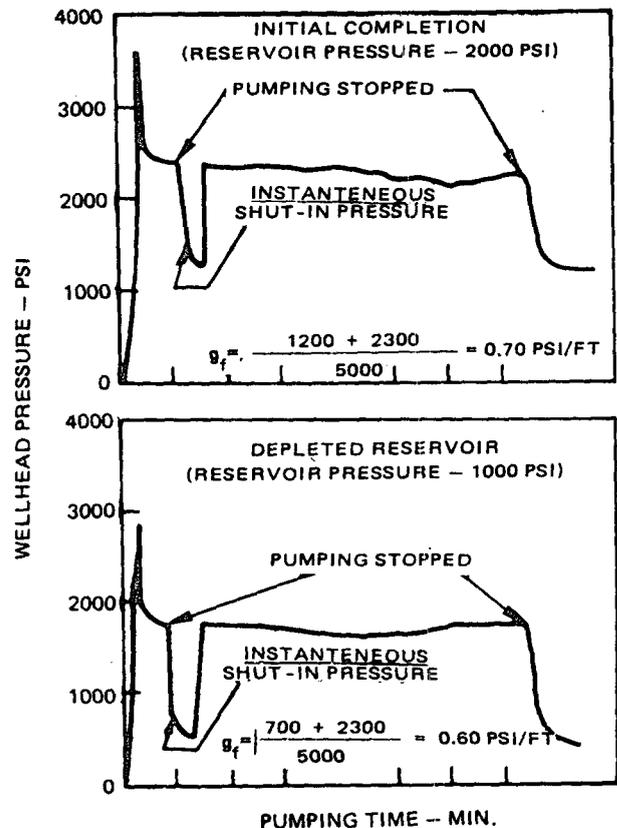

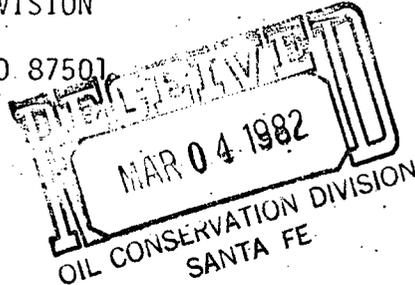

Fig. 7.4—Typical fracture pressure recordings.

Gentlemen:

I have examined the application for the:

Petro-Lewis Corp.      L. G. Warlick      No. 1-A      19-21-37  
Operator      Lease and Well No.      Unit, S - T - R

and my recommendations are as follows:

O.K.----J.S.

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

Yours very truly,

/mc
