## **EXECUTIVE SUMMARY**

At the request of the New Mexico Oil Conservation Division (New Mexico OCD), Mack Energy Corporation (Mack Energy) was asked to determine the capacity of the Berry 'A' Federal Brine Well (Berry 'A') prior to the wells plugging and abandonment.

Subsurface Technology Inc. (Subsurface) simulated the approximate cavern size and configuration using the commercially available Visual SalGas, Version 2.0 (SalGas).

The results of the simulation indicated a cavern size of approximately 49,973 barrels. The maximum radius of the cavern was determined to be approximately 33 feet at a depth of 586 feet.

## **1.0 INTRODUCTION**

Mack Energy retained Subsurface to model the approximate cavern capacity and configuration of the Berry 'A' brine production well.

Mack Energy plans to plug and abandon the brine production well. The New Mexico OCD requested Mack Energy to determine the capacity of the brine well prior to commencing the plugging operations.

Several methods were considered as to how best to satisfy this request. Conducting a sonar caliper survey was initially considered. However, the Berry 'A' brine production well is completed with a 2-3/8-inch fresh water injection string set at 590 feet. There are no sonar tools currently available in the United States capable of conducting a through-tubing sonar survey in pipe of this size. To conduct a sonar caliper survey, the 2-3/8-inch injection string would have to be removed from the well.

The second method considered and agreed upon by the New Mexico OCD and Mack Energy was the use of the numerical leaching simulator SalGas to approximate the cavern size and configuration.

## **2.0 HISTORY AND DESCRIPTION OF THE SALGAS NUMERICAL SIMULATION LEACHING MODEL**

The flow mechanism in a solution-mined cavity being developed through water circulation varies as the operation continues. Based on various laboratory experiments and the related empirical relations, a numeric leaching model was developed in 1974 (Saberian, 1984).

In 1977, cavern hydraulics calculations were added to the original leaching modeling followed in 1978 with the integration of gaseous pad calculations thus resulting in the creation of the original version of the numerical leaching model SalGas.

The original version of SalGas ran on a mainframe computer and used punch cards for data input. In 1990, Ahmed Saberian configured the original version so that it could

be run on a personal computer. In 1994, Version 2.0 of SalGas was introduced and is the current version of the numerical leaching simulator.

A graphical user interface (Visual SalGas) was developed and incorporated into the leaching simulator in 1994 and provides a menu-based generator for the data input files. SalGas can now be executed from the Visual SalGas interface through a windows environment. The graphical user interface has been improved and upgraded since its initial introduction. The current version is Visual SalGas, Version 1.5 and was used in the numeric leaching simulation of the Berry 'A' brine production well.

SalGas simulates the mining operation by dividing the cavern into a series of circular disks (computational cells) and stacks these disks on top of each other. User defined time increments are input into the model. These time increments are further divided into smaller time increments. Upon initiation of SalGas, the model calculates the salt dissolution and fluid flow in the bottom cell for the first time increment and then for each of the cells above the bottom cell. This cycle is repeated for each of the user defined input times. The simulation is run under isothermal conditions with a temperature of 75°F applied throughout the simulated system.

At the end of the simulation run, a report is generated that includes pertinent information from the simulation such as specific gravity of the produced brine, the radius of the individual cells, total water injected, total brine produced, etc.

Detailed information about the model, theories and formulas used, programming description, flow charts, and model validation are available upon request.

### **3.0 HISTORY OF THE BERRY 'A' FEDERAL BRINE WELL**

On June 26, 1998 while drilling the Berry 'A' brine production well, brine water was encountered at approximately 588 feet. The well was completed open-hole from 425 feet (8-5/8-inch cemented casing shoe) to 646 feet (total depth). One thousand ninety six (1,096) barrels of brine were then produced from the well through January 1, 1999.

On June 29, 1999, the well was deepened to 696 feet and a submersible pump was set at 599 feet. Between July 1, 1999 and January 1, 2000, ninety seven hundred (9,700) barrels of brine were produced from the Berry ‘A’ brine production well. Operations were then suspended until August 17, 2001.

On August 17, 2001, a 2-7/8-inch injection string was set at 599 feet. Fresh water was injected down the tubing and brine was produced through the tubing-casing annulus.

On November 2, 2001, the 2-7/8-inch hanging string was removed from the well and replaced with a 2-3/8-inch injection string. The 2-3/8-inch injection string was run to a depth of 590 feet in the well. Brine was extracted from the Berry ‘A’ brine production well via the solution-mining method through 2006. A total of 305,133 barrels of brine water were solution-mined from the Berry ‘A’ brine production well.

The volumes of brine produced and fresh water injected into the Berry ‘A’ brine production well are summarized in Table I. The current wellbore schematic is presented in Figure 1.

#### **4.0 REVIEW OF MODELING PARAMETERS AND SIMULATOR CONFIGURATION**

The modeling parameters used in the simulation were derived from the information supplied by Mack Energy.

The Berry ‘A’ brine production well was used on an intermittent basis throughout the production history of the well. The production volumes supplied were the yearly total volumes of brine produced and fresh water injected. These volumes were converted to average yearly flow rates in gallons per minute (gpm) between 2001 and 2006.

The total volume of brine produced (10,796 barrels) during the time that the well flowed naturally and during the time that a submersible pump was used to produce brine water, were not included in the simulation as no fresh water was injected and little, if any, solution-mining would have occurred.

The LithoDensity, Compensated Neutron/Gamma Ray log of the offset well, Berry 'A' Federal No. 9, was reviewed for pertinent geologic data regarding the salt formation that the Berry 'A' brine production well is completed in.

The log indicates the top of the salt to be at approximately 485 feet and extends through the total depth of the well at 696 feet. The interval where the initial production of brine occurred (through natural flow and pumping) is indicated on this log between 590 feet and 610 feet.

Another break in the salt sequence is indicated between 655 feet and 610 feet. The increase in the gamma ray response could either be a shale sequence or possibly a potassium carbonate (potash) layer in the salt.

In order to provide a conservative estimate (maximum size) of the cavern capacity, the entire salt interval between 485 feet and 696 feet was assigned a dissolution factor of 1.0.

The increase in the dissolution factor caused by the preferential dissolution of possible potash layers in the salt was not taken into account in the simulation. Additionally, a decrease in the dissolution factor due to any shale sequences in the salt was not accounted for in the simulation either. Thus, the possible effects that either condition might have on the cavern size during the simulation are counterbalanced. A reproduction of a portion of the LithoDensity, Compensated Neutron/Gamma Ray log is included as Appendix A.

The Berry 'A' brine production well was completed with the 8-5/8-inch cemented casing string set at 425 feet which is in the shale layer above the top of the salt at 485 feet. To avoid solution-mining this shale layer, the 8-5/8-inch cemented casing string in the simulation runs was lowered to the top of the salt at 485 feet and an incompressible pad was placed at this depth. Configuring the simulator in this fashion prevents the unwanted dissolution of the shale sequence above the top of the salt.

The initial simulation run was conducted with the 2-7/8-inch injection string

positioned at 599 feet. The fresh water injected was assigned a specific gravity of 1.0. The initial specific gravity of the produced brine was assigned a value of 1.176 (9.8-ppg brine as recorded by Mack Energy). The cavern was divided into one-foot increments (computational cells) with an initial borehole radius of 0.3177 feet. The initial leaching simulation at 599 feet was run for 78 days.

The simulation was then restarted using the cavern size and brine specific gravity at the individual cavern depths as calculated from the initial 78-day simulated leaching period. A 2-3/8-inch injection string was positioned at 590 feet and the cavern was again divided into one-foot increments. The simulation was restarted and run for an additional 1885 days. The 1885-day injection period was further divided into six yearly time segments with individual brine production rates assigned to each segment. The production rates were derived from the total amount of brine produced during the particular year modeled.

Table II summarizes the selected input values used in the leaching simulation.

## 5.0 SIMULATION RESULTS

The results of the final simulation indicate a total cavern volume of 49,973 barrels with a maximum radius of 33 feet at a depth of 586 feet. The amount of brine produced from the simulation was 305,009 barrels which is comparable to the total reported amount of brine produced (305,133 barrels).

The amount of fresh water injected as calculated from the simulation was 316,021 barrels. A volume of 381,416 barrels of fresh water was reported injected during the duration of the solution-mining operations. It is suspected that the excess fresh water that was reported used during the leaching operations was lost to the depleted salt water producing interval between 590 feet and 610 feet.

The reported amount of brine water produced was 305,133 barrels. One barrel of saturated brine water contains approximately 123.09 pounds of salt (Halliburton, 2001). Therefore, approximately 37,558,821 pounds of salt were produced during the solution-mining operations. One cubic foot of salt weighs approximately 135 pounds,

thus, the amount of salt produced was approximately 278,213 cubic feet. Converting cubic feet to barrels (0.1781 cubic feet per barrel) yields a cavern volume of 49,550 barrels which compares favorably to the simulated cavern volume of 49,973 barrels.

The results from the leaching simulation are summarized in Table III. A graphical representation of the simulated cavern configuration during each year of the solution-mining process is presented in Figure 2. The output files generated from the leaching simulation are presented in Appendix B.

## 6.0 CONCLUSIONS

The cavern volume derived from actual field data compares favorably with the value generated from the SalGas leaching simulator, thus indicating the simulated cavern volume of 49,973 barrels represents a reasonable approximation of the cavern size.

With the submittal of this document to the New Mexico OCD, all requirements for determining the approximate capacity of the Berry 'A' brine production well will have been satisfied.

## APPENDIX B

### Input Data

Depth to Oil Pad (feet) 485.00  
 Depth to Bottom of Injection Tubing (feet) 599.00  
 Salt Thickness Exposed to Active Dissolution (feet) 114.00  
 Outside Diameter of the Casing (inches) 8.62  
 Outside Diameter of the Injection String (inches) 2.88  
 Specific Gravity of Salt 2.16  
 Number of Disc-Shaped Computational Cells 114.00  
 Injection Level at Computational Node Number 1.00  
 Production Level at Computational Node Number 115.00  
 Number of Cavity Physical Data Print Outs 1.00  
 Production Data Print Frequency 1.00  
 Specific Gravity of Fresh or Saline Injection Fluid 4.00

### Rate Data
