1.0 INTRODUCTION

Navajo Refining Company (Navajo) manages an inactive 2.2-acre nonhazardous landfarm known as the Truck Bypass Landfarm (TBL) at its refinery process area in Artesia, New Mexico. The TBL was formerly used for the treatment of various nonhazardous hydrocarbon-contaminated solid wastes. The unit has undergone routine annual soil monitoring since 1993.

The current document presents the results of annual soil monitoring activities conducted on February 1, 1995. This report presents sampling activities, laboratory analytical results and findings, and recommendations associated with this most recent round of monitoring activities at the TBL.

2.0 SOIL SAMPLE COLLECTION AND ANALYSIS PROCEDURES

The following sections summarize methods and procedures used to:

- Identify sample locations;
- Collect soil samples from those locations;
- Characterize and document subsurface soil conditions observed at the time of sampling; and
- Evaluate the samples at the analytical laboratory.

2.1 Sample Locations

Nine soil sample locations at the TBL were selected on the superimposed grid pattern employed for previous sampling events at the unit. Sample locations were randomly selected from the available grid points (excluding those grid points already used as sample locations during earlier sampling events). Soil sample locations for the February 1995 sampling event are presented in Figure 2-1 along with locations for the representative background sample and samples obtained during prior sampling events.

2.2 Sample Collection Procedures

At each sample location, a drilling rig was used to advance an 8-1/4 inch OD hollow stem auger containing either a split-spoon sampler or a 5-foot core-barrel recovery tube to a target final boring depth of 7 feet. Because of restricted drilling rig clearances at the surface, the split-spoon sampler was used from 0 to 2 feet, with the core-barrel tube used for the deeper samples. Soil samples were obtained at specified depth intervals, and observations concerning soil conditions across the soil profile at each boring location were recorded in boring logs (Appendix A).

Samples were obtained from the following intervals (as measured below surface grade): 1-2, 3-4, 4-5, 5-6, and 6-7 feet. Exceptions to this scheme included boring locations A-7 and A-9. At these locations, sample collection intervals were altered slightly either in response to a lack of sample recovery in a target interval or observation of pronounced differences in soil stratigraphy within a sample interval, which warranted further subdivision of a targeted interval.

Following recovery of soil samples at each location, the coring tubes were opened and samples immediately collected at the specified intervals. All samples were listed on

accompanying chain-of-custody forms. The samples were placed in appropriate sample containers, stored in ice-insulated coolers, and shipped via overnight delivery to the designated analytical laboratory. Copies of the sample chain-of-custody forms are included in Appendix B of this report.

Samples for photoionization detector (PID) analysis were collected and placed in clean pint glass jars. When one-half full with soil, the jar was sealed with aluminum foil and capped. The jars were stored overnight at room temperature. To obtain PID readings, the cap was removed and a special Teflon™ cap was screwed into place. The special cap has two tubes to connect with a Thermo Environmental OVM 580 PID meter so that organic vapors are measured in a closed loop without dilution to maximize sample readings and reproducibility. After meter calibration, the tubes were hooked to the meter and the other ends were pushed through the aluminum foil to obtain a sample reading. The readings were recorded on the sample borehole logs (Appendix A).

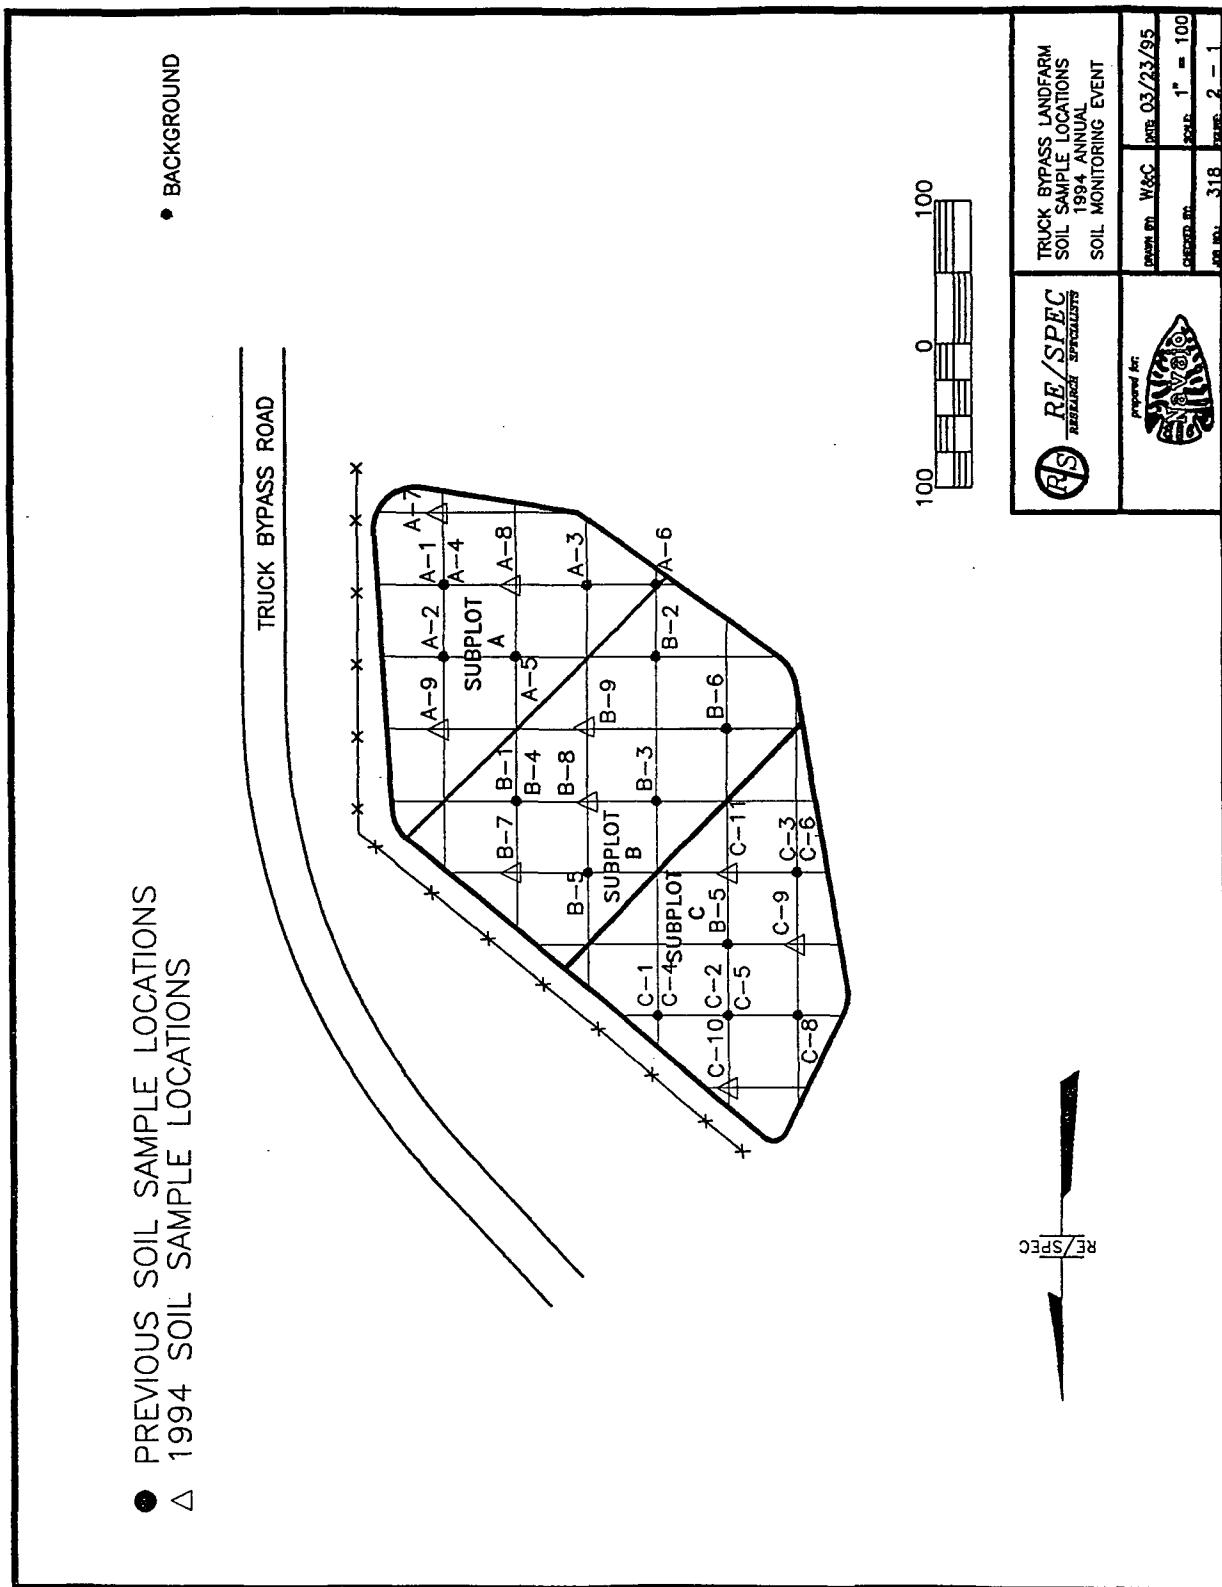

Figure 2-1 Truck Bypass Landfarm Sample Locations,
1994 Annual Soil Monitoring Event

3.0 SAMPLE ANALYSIS AND RESULTS

3.1 Sample Analyses

Soil samples collected from the TBL were analyzed for the following parameters and constituents:

- pH: SW-846 Method 9045
- electrical conductivity (EC): SW-846 Method 9050
- oil and grease: SW-846 Method 9071
- arsenic: SW-846 Method 7061A
- chromium, lead, nickel, and zinc: SW-846 6010A
- volatile organics: SW-846 Method 8240
- semivolatile organics: SW-846 Method 8270

Results of the laboratory analyses (presented in Appendix B and summarized in Table 3-1) are described in the following sections.

3.2 General Soil Chemistry Data

General chemistry parameters for which soil samples were evaluated included pH and EC. As was the case for previous sampling events, data for soil pH again illustrates that unit soils are best described as slightly alkaline throughout the soil profile. Soil EC values indicate moderate soil salinity conditions across the unit with the exception of locations B-7 and B-9, which exhibited relatively elevated EC values of 15.2 and 14.2 mmhos/cm, respectively (Table 3-1).

3.3 Soil Metal Concentrations Data

Soils metal concentration data yielded results that are highly consistent with previous soil sampling events conducted at the unit. Reported soil arsenic concentrations ranged from 3.2 to 42.2 mg/kg in the 1-2 feet interval, with underlying intervals generally exhibiting concentration values similar to background. However, at boring locations A-7 and A-8, discrete intervals were identified at depth in which arsenic was observed to be moderately elevated (soil concentrations ranging from 10.9 to 21.6 mg/kg). At the 4-5 and 5-6 feet sample intervals at location A-8, arsenic concentrations of 19.2 and 21.6 mg/kg were obtained, respectively. However, as samples obtained from these intervals also exhibited significant oil and grease levels while overlying and underlying intervals did not,

Notes:

¹ Benzene, Ethylbenzene, Toluene, Xylene (BETX) detection limit shown. Detected constituent abbreviations: E - ethylbenzene, M - methylene chloride, MEK - methyl ethyl ketone, TCA - 1,1,1 trichloroethane, X - total xylenes.

² Polycyclic Aromatic Hydrocarbon (PAH) detection limit shown. PAH's include acenaphthene, acenaphthylene, anthracene, (a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, benzo(g,h,i)perylene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, ideno(i,2,3-cd)pyrene, naphthalene, phenanthrene, and pyrene. Detected constituent abbreviations: D - Di-n-butylphthalate, J - identified but below detection limit.

the elevated arsenic concentrations are most likely associated with earth materials deposited in place during previous earth-moving and construction activities associated with the unit.

Elevated soil lead concentrations were primarily restricted to the uppermost 1-2 feet sample interval (Table 3-1). However, as was the case for arsenic, elevated lead concentrations reported at significant depth were associated solely with borings A-7 and A-8, at the same sample intervals in which elevated arsenic concentrations were also observed.

For the remaining inorganic constituents of concern (chromium, nickel and zinc) the analytical results indicate either that elevated constituent concentrations are present in unit soils, but at levels which could not be construed to indicate a potential environmental risk (chromium), or that unit soils have otherwise not been impacted by the constituents (nickel and zinc).

3.4 Soil Organic Concentrations Data

Oil and grease concentrations in the 1-2 feet soil sample interval ranged from less than 0.1 to 17.6 percent, with an overall average of 9.2 percent (Table 3-1). The data and associated boring logs generally indicate that hydrocarbon materials present at deeper sampling intervals resulted from direct physical placement rather than by migration through the soil profile.

Volatile organic constituent detections in TBL soil samples were limited primarily to apparent laboratory artifact detections (Table 3-1). Methylene chloride was detected in trace levels in 14 samples, methyl ethyl ketone in one sample, and di-n-butylphthalate in one sample.

Ethylbenzene and xylene were reported at 2 and 6 mg/kg, respectively, in the soil sample collected at Boring A-7 at the 4-4.5 feet interval. As discussed above, the available evidence indicates that the presence of these constituents are contained within a discrete soil interval that originates from historical earth-moving activities rather than from constituent migration from overlying strata.

A single detection of xylene at 40 mg/kg was reported in the sample obtained from the uppermost 1-2 feet interval of boring C-10.

A single detection of 1,1,1-trichloroethane was reported at a trace concentration of 0.009 mg/kg for the soil sample obtained from Boring B-7 at the 5-6 feet interval (Table 3-1). This constituent is not a typical petroleum constituent or refinery process byproduct, and the validity of this detection is uncertain. However, 1,1,1-trichloroethane has a very low solubility in water. If indeed present in unit soils, the limited occurrence

and minimal concentration reported for this constituent indicates no grounds exist for environmental concern.

With the exception of one artifact detection of di-n-butylphthalate, no semivolatile organic constituents were reported in soil sample analyses. It is possible, if not probable, that various semivolatile constituents are present in some of the hydrocarbon-containing oils present at the unit. However, in those samples in which semivolatile constituents would most likely be present due to heavy concentrations of oil and grease materials, analytical detection limits were also elevated due to matrix interference resulting from those same hydrocarbon compounds.

The PID readings included with the boring logs (Appendix A) were examined to compare the results with the laboratory results. PID results show significantly elevated levels (> 100 ppm) near and within five feet of the surface (borings A-7, A-9, C-9 and C-10), or at depth (A-9). However, the results do not correlate particularly well with the laboratory results for the aromatic volatiles. Of the six readings greater than 100 ppm, only two samples (A-7 [4-5'], C-10 [1-2']) had detectable volatiles. Two of the highest readings were from samples at depth (A-9 [5-6'], A-9 [6-7']) which had low detection levels for volatile and semivolatile hydrocarbons. Presence of elevated PID readings at depth is indicative of proximity to petroleum hydrocarbons from previously documented unrelated releases at the facility.

As a final note, during the previous two rounds of soil monitoring activities at the TBL, acetone was detected in 11 and 17 soil samples, respectively. Those detection events were considered to be apparent artifacts, although the analytical laboratory was unable to provide any reason why or how acetone might have been introduced into the environmental samples at that time. Acetone was not detected in any of the samples analyzed during the current round of sampling and analyses.

4.0 DISCUSSION AND RECOMMENDATIONS

The analytical data and observations generated by this most current round of soil sampling at the TBL further confirms the results of previous environmental investigations conducted at the unit. To summarize briefly, surface soils at the unit contain relatively immobile heavy-end hydrocarbons and inorganic metal constituents introduced during past surface applications of nonhazardous hydrocarbon waste materials. Subsurface soils below the first few feet of the unit have generally remained either unaffected by past operations at the unit, or else exhibit moderate levels of hydrocarbon and metal contamination that apparently result from historical site activities which predate the installation of the TBL. Soils at depth (in excess of 5-7 feet) also have been impacted by unrelated petroleum product releases in other areas of the facility that are being addressed under New Mexico state programs.

None of the observations or data obtained to date suggest that waste materials contained in unit soils pose a threat to underlying groundwater, nor is there any feasible potential for public contact with unit soils. Consequently, there is no indication that current environmental conditions at the unit pose any significant environmental risk.

The TBL has not routinely received hydrocarbon materials since 1993 and has been completely inactive since September 1994. During that time, remedial activities in the form of soil tillage and nutrient applications have been conducted on a routine and ongoing basis. Subsurface soils at the TBL have been subject to extensive environmental investigation over the past several years and are now well characterized. Repeated soil sampling events conducted at the unit have yielded consistent observations and data. Consequently, Navajo can foresee no rational reason why the annual soil monitoring program should proceed in its current form.

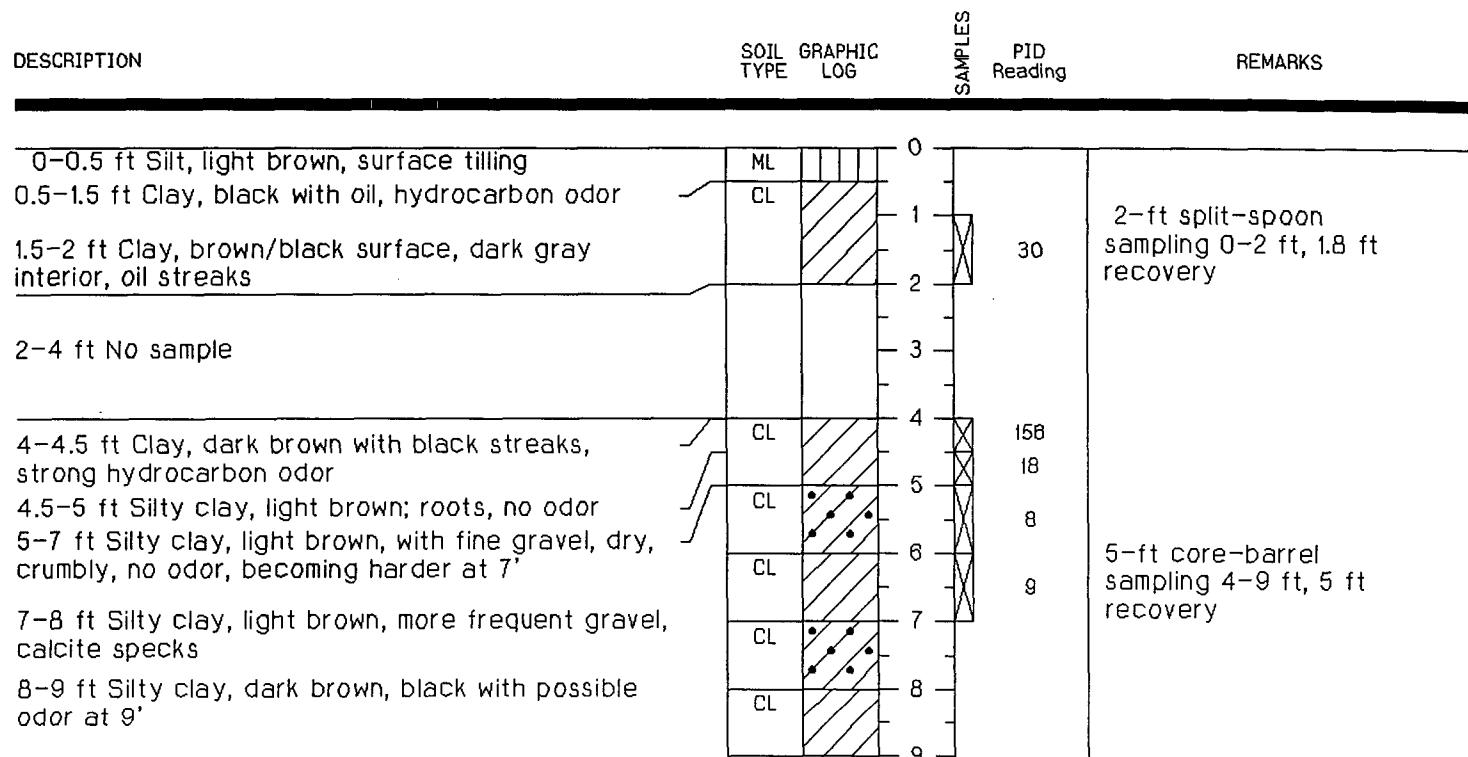

Specifically, Navajo recommends that future annual monitoring events conducted during the interim period preceding unit closure be limited to analysis of soil oil and grease levels needed to track the progress of hydrocarbon remediation activities. It is also recommended that soil sample depth intervals be limited to 0-1 and 1-2 feet below surface grade, but that the total number of sample locations be upgraded from 9 to 12 locations (four per subplot for a total of 28 oil and grease samples).

Albuquerque, New Mexico 87110-3927

March 10, 1995

Dear Mr. Boyer,

On February 3 and 4, 1995, fifty-three soil samples and two trip blanks were received, cool and intact, by Inter-Mountain Laboratories - College Station. The samples were identified by project name "Truck Bypass Landfarm". Analyses for Volatiles, Semivolatiles, pH, Oil & Grease, electrical conductivity, and Metals were performed as requested on the accompanying chains of custody.

It is the policy of this laboratory to employ, whenever possible, preparatory and analytical methods which have been approved by regulatory agencies. The methods used in the analysis of the sample reported here are found in "Test Methods for Evaluating Solid Waste", SW-846, USEPA, Final Update I, July 1992. All reports in this package reference the methods utilized.

The majority of the soils were analyzed in Bozeman for volatiles, after we had problems with our GC/MS instrument. The samples were extracted with methanol and the extracts sent to Bozeman. With the delays in shipping, several samples were analyzed past established holding times. A few samples were analyzed within holding times, but at high dilutions. These samples were reanalyzed at lower dilutions, and these results were reported.

Quality Control reports have been included for your information and use. These reports appear at the end of the analytical package and may be identified by title. If there are any questions regarding the information presented in this package, feel free to call at your convenience.

Sincerely,

Ulonda M. Rogers

Reference: Method 8240A: Gas Chromatography / Mass Spectrometry for Volatile Organics Test Methods for Evaluating Solid Waste, SW - 846, Final Update I, United States Environmental Protection Agency, July 1992.

Comments: A capillary column is used instead of a packed column as in the reference above. Sample results are calculated on a dry weight basis. Methylene chloride is a common laboratory contaminant. Analytical results should not be considered reliable unless the sample results are 5 times the reporting limit or 10 times the blank concentration.

Comments: A capillary column is used instead of a packed column as in the reference above.
Sample results are calculated on a dry weight basis.
Methylene chloride is a common laboratory contaminant. Analytical results should not be considered reliable unless the sample results are 5 times the reporting limit or 10 times the blank concentration.

Laboratory ID: 0695G00451

Report Date: 02/25/95
Date Analyzed: 02/17/95

Tentative Identification	Retention Time (Minutes)	Concentration* (mg/Kg)
Hydrocarbon envelope	15 to 37	

* - Concentration calculated using assumed Relative Response Factor = 1.

Quality Control:

<u>Surrogate</u>	<u>Percent Recovery</u>	<u>Acceptance Limits</u>
2 - Fluorophenol	60%	25 - 121%
Phenol - d5	68%	24 - 113%
Nitrobenzene - d5	70%	23 - 120%
2 - Fluorobiphenyl	80%	30 - 115%
2,4,6 - Tribromophenol	80%	19 - 122%
Terphenyl - d14	79%	18 - 137%

References:

Method 3550: Sonication Extraction.
Method 8270: Gas Chromatography / Mass Spectrometry for Semivolatile Organics
Test Methods for Evaluating Solid Wastes, SW - 846, Final Update I, United States
Environmental Protection Agency, July 1992.

Comments: Elevated detection limit due to matrix interference.

Client: **NAVAJO REFINING COMPANY**
Project : Truck Bypass Landfarm
Sample ID: Boring B-7 6-7'
Laboratory ID: 0695G00454

Report Date: 03/06/95
Date Sampled: 02/01/95
Date Analyzed: 02/10/95
Time Analyzed: 8:30 AM

Tentative Identification	Retention Time (Minutes)	Concentration* (mg/Kg)
Hydrocarbon envelope	20-26	

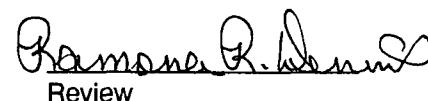

* - Concentration calculated using assumed Relative Response Factor = 1

Quality Control: Surrogate Percent Recovery Acceptance Limits
1,2-Dichloroethane-d4 106% 70 - 121%
Toluene-d8 100% 81 - 117%
Bromofluorobenzene 90% 74 - 121%

Reference: Method 8240A: Gas Chromatography / Mass Spectrometry for Volatile Organics Test Methods for Evaluating Solid Waste, SW - 846, Final Update I, United States Environmental Protection Agency, July 1992.

Comments: A capillary column is used instead of a packed column as in the reference above. Sample results are calculated on a dry weight basis. Methylene chloride is a common laboratory contaminant. Analytical results should not be considered reliable unless the sample results are 5 times the reporting limit or 10 times the blank concentration.

Comments: A capillary column is used instead of a packed column as in the reference above.
Sample results are calculated on a dry weight basis.
Methylene chloride is a common laboratory contaminant. Analytical results should not be considered reliable unless the sample results are 5 times the reporting limit or 10 times the blank concentration.
