Onsite Sampling Investigation

1984

During the week of March 19-24, the Field Investigation Team (FIT) from the Dallas office of Ecology and Environment, Inc. conducted a sampling investigation of the Plateau Inc. Refinery (NM1686) located just southeast of Bloomfield, New Mexico. Samples were taken according to a plan developed by Steve Schwartz and Will Focht, both of the US EPA Region VI office in Dallas. Entry onto the site was by permission from Mr. Paul Liscom, Refinery Manager. During all FIT activities on the refinery property, Plateau employees accompanied the individual work teams.

Site Description

The refinery now owned by Plateau Incorporated has been in existence since before 1960. The 287 acre refinery property extends across the San Juan River which flows from east to west, 1/8 mile north of the actual refinery plant (see attached location map).

The San Juan river has cut a wide stream path leaving an exposed north facing bluff and talus slope. The principle strata are an impermeable shale known as the Nacimiento Formation (80-100') and an overlying reworked glacial cobble bed (40-50'). Alluvial sands are layered above the cobble bed. The interface between the cobble bed and shale is very distinct and demonstrates differential permeabilities that vary by several orders of magnitude.

Below the bluff and directly north of the refinery plant lies a broad sandy river terrace that ranges up to 150 feet wide, and usually only 2-3 feet above the river level. Flow in the San Juan River is controlled by operation of the Navajo Dam 26 miles upstream. Groundwater level in the sand terrace varies with river flow conditions. Depth to first aquifer of major proportions is about 700 feet; production is about 200 gpm.

In several locations along the bluff, seepages and springs issued from the cobble bed/shale interface. The talus slope exhibited obvious staining and discoloration and there was evidence of distressed vegetation at its base. Stained soils and seepage from the bluff had distinct hydrocarbon odors. A large area of the west end of the river terrace was stained darkly. This was reportedly from a previous spill of 2500 barrels of oil in 1963.

FIT Activities

The FIT took samples by standard FIT procedures from the facility's API separator pond, evaporation ponds, monitoring wells, spray irrigation area and from a variety of features on the property that were in probable runoff paths (ponds, sumps, arroyos, etc). For comparison, samples were taken upstream and downstream of the refinery in both the San Juan River and Hammond Ditch. Samples were also taken of seepage from the bluff and soils from the river terrace (see Attachment A for sample station locations).

The principal leachate sampled as Station #18 produced an immiscible, two-phase liquid that was field-estimated to be 5% organic liquid and 95% water. This sample was field separated by a FIT chemist. The water fraction was sent to the designated contract laboratory while the organic liquid fraction was sent to EPA's National Enforcement Investigation Center (NEIC) in Denver, Colorado for further handling.

Several shallow (1-3') holes were dug in the river terrace. After allowing groundwater to percolate into the holes, the air volumes in the holes above the groundwater surface were monitored with an HNu photoionizer. A sample of the liquids from each hole was gathered in a jar from which the head-space was also monitored. Readings in the holes varied from 100-200 ppm in benzene equivalent; and in headspace from captured liquids, 200-550 ppm benzene equivalent.

#### Summary

Contaminants present in samples from the spray irrigation area (Stations 05,06) consisted primarily of solvents and unknowns.

The landfarm area (Stations 07,08) contained polynuclear aromatics, alkanes and unknowns.

The truck area sump (Station 11) showed polynuclear aromatics, aromatic solvents, alkanes, substituted benzenes, and unknowns.

The evaporation ponds (Stations 12A,12B,13A,13B) showed phenols, polynuclear aromatics, aromatic and non-aromatic solvents, alkanes and unknowns.

The sump east of the evaporation ponds (Station 14) showed polynuclear aromatics, pentachlorophenol, and unknowns.

Samples from the landfill (Stations 15,16) contained polynuclear aromatics, solvents, alkanes, substituted benzenes, unknowns, and metals.

API pond samples (Stations 23,24,25) showed phenols, polynuclear aromatics, solvents, alkanes, unknowns, substituted benzenes and metals.

EPA samples of the API separator showed substituted naphthalenes and creosols in addition to the previously noted compounds.

The pond north of the API pond (Station 26) showed polynuclear aromatics, unknowns and metals.

All samples collected from the Hammond Ditch (Stations 01-04) showed contamination. Station 02 showed the highest contamination (unknowns and polynuclear aromatics). Off-site migration is well documented by the alkanes in Station 04, the down stream sample.

Stations 09, 10, 17 and 20 all show some contamination coming from the site however levels are much lower than those in leachates and the terrace stain (Stations 18 and 19). The Station 18 sample is also different in that it contains lower molecular weight components more characteristic of refined products.

Of the 3 wells sampled, Well #4 (Station 27) shows heavy contamination with alkanes. Well #1 (Station 29) is clear of organics.

Samples collected from the river, (Stations 21 and 22) show little if any contamination from the site. Present in both sediment samples, upstream and downstream, are 1,1,1-trichloro and 1,1,2,2-tetrachloroethane. The source of this contamination is unknown.

Since the site is underlain at depth by the impermeable Nacimiento Shale Formation, the most probable scenario has any spilled materials percolating vertically, than following contours of the shale/cobble bed interface northward toward the bluff. The interface reportedly tilts downward gently toward the San Juan River. Motion of the leachate beneath the plant is manifested in seepage and springs emitting from the bluff precisely at the interface. Additional hydrologic impetus likely is given also to the leachates by mounding of any percolated liquids under the refinery. While the cobble bed is highly permeable it still restricts flow, resulting in mounding.

Based on information presented in this report, it is evident that groundwater beneath the plant and groundwater below the river terrace are contaminated with organics and hydrocarbons derived from refinery operations. Further FIT activity at the site would be necessary only to further quantify volumes and delineate probable patterns of groundwater migration.

Data on existing Plateau Inc. wells and physical measurements of water samples are shown at Tables 1 and 2 respectively. Results of all FIT sampling have undergone QA/QC and are summarized in this report at Attachment B. Results of sampling by EPA personnel are at Attachment C. Chain-of-Custody documentation for this effort is also attached.

Polynuclear aromatic hydrocarbons include naphthalene, fluorene, phenanthrene, anthracene, 2-methyl naphthalene, fluoranthene, benzo(a) anthracene, pyrene, benzo (b) fluoranthene, benzo (k) fluoranthene, acenaphthene, chrysene, benzo (ghi) perylene, dibenzofuran and ideno (1,2,3-cd) pyrene.

Aromatic solvents include benzene, toluene, ethyl benzene and xylenes.

Phenols include phenol, 4-methyl phenol, 2-methyl phenol, and 2,4-dimethyl phenol.

Other solvents include acetone, carbon disulfide, vinyl acetate, 2-hexanone and 2-butanone.

Metals are listed if sample concentration appears to be elevated in comparison to other samples in the same matrix (soil, water).
