Mr. Hansen:

Phone:
432 687-5400

On behalf of Rice Operating Company (ROC), ARCADIS is submitting this 2011 Monitor Well Report for the Hobbs Salt Water Disposal (SWD) System N-6 Release Site. The site is located immediately south of the intersection of Highway 62-180 and the South Loop of the Hobbs West County Road Bypass.

Email:
shall@arcadis-us.com

ROC was the service provider (agent) for the Hobbs SWD System and has no ownership of any portion of the pipeline, well or facility. The Hobbs SWD System was owned by a consortium of oil producers, System Parties, who provide operating capital on a percentage ownership/usage basis. The Hobbs SWD System has been abandoned.

Our ref:
MT000821.0001

Groundwater Sampling

Wells are sampled quarterly in accordance with NMOCD guidelines. The attached tables summarize the analytical results from groundwater samples collected from the monitor wells in 2011 and depth to water, total depth of the well, volume of water in the wellbore and volume of water purged from the well.

A monitor well (MW-3R) was drilled on November 15, 2010. The well was drilled for comparison to well MW-3.

Imagine the result

Generally, total dissolved solids (TDS) and sulfate concentrations in groundwater yielded from the Ogallala in southern Lea County range from 400-600 milligrams per liter (mg/L) and 40-215 mg/L, respectively. Water yielded from the Triassic red-beds exhibit a different geochemistry than that of the Ogallala. TDS and sulfate concentrations in groundwater yielded from the Triassic red-beds range from 635-800 mg/L and 200-335 mg/L, respectively. (Groundwater Report 6; Geology and Ground-water Conditions in Southern Lea County, New Mexico; Nicholson and Clebsch).

MW-3 was drilled to a depth of 165 feet bgs and encountered the red-bed at a depth of 160 bgs. The well is screened from a depth of 105 feet to 155 feet bgs, within five feet of the top of the red-bed. The other wells at the site are screened at the top of the Ogallala aquifer in the primary water bearing unit. They are generally screened from a depth of approximately 30 to 55 feet bgs.

At the N-6 site, the source of chloride impact was removed in 1994 and groundwater recovery to remove chlorides was initiated in 1996, yet MW-3 continues to exhibit elevated chloride, total dissolved solids (TDS) and sulfate concentrations.

Chloride, TDS and sulfate concentrations in MW-3 are markedly higher than the other wells at the site and are strongly indicative of naturally occurring geochemical conditions at the base of the Ogallala where it overlies the Triassic red-beds. The average sulfate concentration in this well is in excess of 700 milligrams per liter (mg/L) as compared to an average of approximately 139 mg/L in the other wells at the site. The TDS concentrations are all greater than 4,100 mg/L as compared to an average concentration of approximately 650 mg/L in the other wells on site.

Free Product Removal

In 1994, a leak was discovered in a buried SWD pipeline. An assessment program was completed and a free product recovery program initiated. The free product has historically been collected from Monitor Well 1 (MW-1), initially in 1996 in conjunction with groundwater recovery, and then beginning in 2000 with product recovery only.

A biosparge well designed to maximize in-situ biodegradation and minimize volatilization of hydrocarbons was installed at the site and became operational in August 2005. Four borings were drilled on November 8 and 9, 2006 in order to evaluate hydrocarbon occurrence in the vadose zone. Based on drilling observations

a second biosparge well was installed approximately 30 feet east of the original biosparge well. The second biosparge well became operational in March 2007. In November of 2007, an additional eight soil borings (piezometers) were drilled and a third biosparge well was installed southeast of the pump house. These soil borings were located in areas between previous sampling points, outside of the previously identified core source area, and as close as possible to previous (2006) soil borings from which samples had been collected and tested for total petroleum hydrocarbons (TPH) and total organic compounds (TOC).

In November of 2010, the air sparge system at the site was tested by collection of soil gas samples during a cycled shut down. A similar test protocol was previously performed in May/June and September/October 2007, August/September 2008 and November 2009. The soil gas samples from these testing events were analyzed for methane, carbon dioxide, oxygen and benzene, toluene, ethylbenzene and xylenes (BTEX).

During 2011, phase separated hydrocarbon recovery was conducted through biweekly replacement of an absorbent sock placed in the well.

Biosparge Well Operation and Evaluation

Evaluation of the 2007, 2008, 2009 and 2010 soil gas and monitoring well data indicates that the biosparge wells are effective in the remediation of free-phase hydrocarbons at the site. Biochemical results also suggest groundwater chemistry indicative of bioremediation.

We are currently evaluating alternate remedial options to expedite closure of the site.

Thank you for consideration concerning this information. Should you have any questions regarding this submission, please do not hesitate to contact Hack Conder (575 393-9174) or me.

Very truly yours,

ARCADIS
