

## Mid-Study Status

- Layered pressure gives an accurate picture of the depletion in the reservoir. Composite pressure does not.
- Layered pressure data confirms that coal seams are not being equally drained.
- Key questions that remained were:
  - What kind of differential depletion should we expect throughout the HPA?
  - How efficiently will the existing wells drain the differing layers?
  - How much additional recovery will be achieved through infill drilling?
- Reservoir simulation can give an approximate answer to those questions
