## PIERCE A #1A

Mesaverde AIN: 4824101 800' FSL & 1670' FEL Unit O, Sec. 13, T30N, R10W Latitude / Longitude: N36° 48.42' / W107° 49.962'

6/17/03 Bradenhead Repair Procedure

## Summary/Recommendation:

The Pierce A #1A was drilled and completed as a MV producer in 1975. In September 2001 the Lewis interval was added. The 3-month average rate is 220 Mcf/d with cumulative production of 3248 MMscf (11.97 Mstb condensate). In May 2003 production dropped off and the bradenhead started venting gas. It is recommended to set a CIBP over the Lewis perforations, identify the cause of bradenhead pressure, remediate, and place well back on production.

- 1. Comply with all BLM, and BROG regulations. Conduct daily safety meetings for all personnel on location. Notify BROG Regulatory (Peggy Cole 326-9727) and the appropriate Regulatory Agency prior to pumping any cement job. If an unplanned cement job is required, approval is required before the job can be pumped. If verbal approval is obtained, document the approval in DIMS. Allow as much time as possible prior to pump time in case the Agency decides to witness the cement job.
- 2. MOL and RU workover rig. Obtain and record all wellhead pressures. NU relief line. Blow well down and kill with 2% KCI water if necessary. NU BOP with stripping head. Test and record operation of BOP rams. Have wellhead and valves serviced as necessary. Test secondary seal and replace/install as necessary.
- 3. The 2-3/8", 4.7#, J-55 tubing is set at 5584'. Release donut, pick up additional joints of tubing and tag bottom. (record depth.) PBTD should be at +/- 5683'. TOOH with tubing. Visually inspect tubing for corrosion and replace any bad joints. Check tubing for scale and notify operations engineer.
- 4. RU wireline unit. RIH with 4-1/2" CIBP and set at approximately 3866' (top perf is at 3916' and 4-1/2" liner top is at 3240'). Load hole with 2% KCl water. Pressure test casing to 500 psi. Bleed off pressure. If pressure test fails, isolate leak with packer. Contact superintendent and operations engineer for squeeze design. Note: TOC in the 7" casing is at 2100' per the original temperature survey. RD wireline unit.
- 5. Follow squeeze procedure as recommended from Step 4. TIH w/ 7" full-bore packer and set 150' above holes. Pressure up tubing/casing annulus to 500 psi. Establish rate into holes with bradenhead valve open (max pressure 1000 psig). Mix and pump cement. Displace cement to packer. Close bradenhead valve and squeeze cement into holes. Maintain squeeze pressure and WOC 12 hours (overnight).
- 6. TOOH and LD packer. TIH with 6-1/4" bit and drill out cement. Pressure test casing to 500 psig. Test bradenhead valve for flow. Re-squeeze as necessary to hold pressure, or to stop bradenhead flow.
- 7. TIH with 3-7/8" mill and bit and drill out CIBP. Clean out to PBTD at 5683' with air/mist using a minimum mist rate of 12 bph. TOOH and LD mill and bit.
- 8. TIH with an expendable check on bottom, seating nipple, one joint 2-3/8", one 2'x 2-3/8" pup, then ½ of the remaining tubing. Run a broach on sandline to ensure the tubing is clear. TIH w/remaining tubing and then broach this tubing. Replace bad joints as necessary. Alternate blow and flow periods to check water and sand production rates.
- 9. Land tubing at approximately 5580'. ND BOP and NU WH. Pump off expandable check. Connect to casing and circulate air to assure that expendable check has pumped off. If well will not flow on its own, make swab run to SN. During cleanout operations the reservoir may be charged with air. As a result of excess oxygen levels that may be in the reservoir and/or wellbore, contact the Lease Operator to discuss the need for determining oxygen levels prior to returning the well to production. RD and MOL. Return well to production.
