#495

March 12, 1981

Mr. Carl Ulvog Senior Petroleum Geologist New Mexico Oil Conservation Commission P.O. Box 2086 Santa Fe, New Mexico 87503

Dear Mr. Ulvog:

Enclosed please find Form G-103 for the plugging action on two NMSU test wells.

In confirmation of our telephone discussions, the Form G-103 notifies you of the completion of plugging, and also advises you of a name and number change which records the owner and purpose of the wells in the well name, and uses the State Engineer's well number.

Well NMSU-DG1-LRG 484 formerly was named and numbered NMSU-DG-1 and NMSU-DT-2. It also might have been designated NMSU-2.

Well NMSU-DG2-LRG-485 formerly was named and numbered NMSU-DG-2 and NMSU-DT-1. It also had been designated NMSU-1.

You should have earlier Forms G-103 on these two wells, referring to them as NMSU-DG-1 and NMSU-DG-2, in which I notified you of our intent to repair or plug and abandon. You approved those forms on or about 26 November 1980.

Sincerely yours,

Roy A. Cunniff

Project Director NMSU Geothermal Project

March 12, 1980

Mr. Carl Ulvog Senior Petroleum Geologist New Mexico Oil Conservation Commission P.O. Box 2086 Santa Fe, New Mexico 87503

Dear Mr. Ulvog,

Early in 1979 I received the oral consent of Drs. Chaturvedi and Gunaji of the NMSU Engineering College to use two temperature observation wells, NMSU-DG-1 and <u>NMSU-DG-2</u>, for seismic velocity measurements as part of a Department of Energy funded seismic investigation of the low temperature geothermal field to the east of the NMSU main campus. It was with their full knowledge and consent that small explosive charges were set in these wells, but unfortunately they failed to tell me that the wells were subject to plugging requirements. As the detonation of an explosive charge in a well always carries a significant risk of damaging the well, this lack of communication was an unfortunate oversight.

I have enclosed a copy of a memo to Dr. Chaturvedi giving him the details of the possible damage to the wells. If there is any further information that your office requires regarding this matter, I will be happy to supply it.

Sincerely yours,

Marx

PAUL MORGAN, Associate Professor Departments Earth Sci/Physics

MEMORANDUM

TO: Dr. Lokesh Chaturvedi

FROM: P. Morgan Morgan

SUBJECT: Las Alturas Deep Temperature Test Wells

The caving in holes <u>DT1</u> and DT2 is indeed unfortunate; if I had been informed that these boreholes were subject to plugging regulations I would not have used the holes for seismic velocity measurements. Although the experiments were designed to minimize the risk of caving in the holes, there was always a significent risk that this would occur. In our informal meetings with Dr. Daw in which I requested permission to use the holes for the seismic measurements, no reference was made to the plugging requirement.

We performed shallow tests (~10m) with the seismic charges in the DT2 (west well) with no caving problems. Charges were then set at 90m and 80m with no problems, but after a charge at 70m we found it impossible to re-enter the hole past approximately 70m. We assume there to be a minor blockage at this depth due to the charge.

The same charge in <u>DT1</u> (east well) produced disasterous results. A charge at 190m caused major caving from above, burying the cable we were using for detonating the charges. Attempts to pull the cable free failed, so we set a further charge to break the cable to retrieve what we could. The cable broke free immediately after the charge was detonated, but again was buried at a higher level by caving from above. Two further charges were required to completely free the cable. On the last of these charges the casing subsided down the hole.

My sincere apologies for any problems that may arise because of the blocking of DTl and DT2. If I had known of the plugging requirement I would not have attempted the experiment.

cc: Dr. Daw Dr. Swanberg

1

A total of 173 feet of casing was removed, which had been broken at the 34-feet and 173-feet intervals. A drill rig was used in an attempt to drill around the section from 173 feet of depth to 300 feet, using a 2-inch drill bit. The drill bit encountered another break at 205 feet of depth, and with difficulty, the drilling continued to 245 feet. The drill bit became lodged in the casing at that depth. After several hours, the drill was freed. Because of difficulties in attempting to drill around the broken casing, the drill stem was extracted. A six-inch drill bit was used to enlarge the hole to original diameter down to 173 feet of depth.

Cement was pumped into the hole under pressure, and it was plugged with cement from 245 feet of depth to ground surface. A permanent steel marker was installed.

Work was performed by Cole Drilling Company; completed 11 December 1980.

18. I hereby certify that the information above is true and complete to the best of my knowledge and belief.

proposed work[SEE RULE 20]. Reference is made to a letter from Dr. Lokesh Chaturvedi, Assistant Professor, New Mexico State University, to Mr. Carl Ulvog, Senior Petroleum Geologist, New Mexico Oil Conservation Commission, dated February 12, 1979. This letter forwarded two Form G-103's for two geothermal observation wells NMSU-DG-1 and NMSU-DG-2. The letter notes changes in the location of the two wells from the locations cited in previous correspondence. The locations stated in the Form G-103's of the February 12 letter were the locations where the wells were actually drilled. A subsequent letter from Dr. Paul Morgan of New Mexico State University, dated March 12, 1980, reported damage to the two wells.

This well was drilled as a temperature observation well. It was completed January 4, 1979. Plugging was planned after December 31, 1979. In the course of other research at New Mexico State University, the well was damaged and a portion of the well caved in. The purpose of this Notice is to obtain approval to perform remedial work on the well and then plug and abandon the well. The remedial work will consist of removal of the broken pipe casing and plugging the well with cement from the water table back up to the surface of the ground. All work will be accomplished by a commercial well driller.

18. I hereby certify that the information above is true and complete to the best of my knowledge and belief.

17. Describe Proposed or completed Operations (Clearly state all pertinent details, and give pertinenet dates, including estimated date of starting any proposed work) SEE RULE 203.

Drilling started at this location on 12-27-78 at 10:45 a.m. and was completed on 1/3/79 at 7:00 p.m. The drilling was done by Mr. Larry Johnson of Johnson Drilling Company, Las Cruces. Drilling bit size of 5 1/8 inches was used. The hole was completed with a 2-inch diameter steel pipe placed in the entire length of the well. Total depth drilled for the well was 1000 ft. We are making temperature gradient measurements in the well. The drilling and logging was done under the direction and supervision of Dr. N. N. Gunaji, Director, Engineering Experiment Station, NMSU.

18. Thereby certify that the information above is true and complete to the best of my knowledge and belief.

Mr. Carl Ulvog Hammissia on 6 1970 Senior Petroleum Geologist OIL CONSERVATION DIVISION New Mexico Oil Conservatio P.O. Box 2086 Santa Fe, NM 87503

Dear Mr. Ulvog:

Please find enclosed a copy of a report on the geological and geophysical log interpretations of the two geothermal wells already drilled on NMSU land east of highway I-25 in Las Cruces.

We are planning to drill a third well, to be called NMSU-DG-3. The purpose of this well is to test the quality and quantity of hot water at 750 ft. to 850 ft. depth, for possible future use by the University. This well will be located near NMSU-DG-2 (see attached map for location). On the basis of experience gained from the previous two wells, we expect a water temperature of 60 to 65°C in this new proposed well.

Kindly also find enclosed forms G-101 and G-102 for permission to drill the new well. We will appreciate it if you could grant us the permission at your earliest convenience.

With best personal regards.

Sincerely yours,

alunver-

ABSTRACT

After careful site selection, two exploratory geothermal wells were drilled on New Mexico State University property in southeastern part of Las Cruces. One of the wells was drilled to a depth of 1200 ft. and the other to 1000 ft. Both wells encountered groundwater table at a depth of 265 feet. An analysis of lithologic log and geophysical logs viz. Resistivity, Spontaneous Potential, Caliper, Gamma Ray, Neutron Porosity and Densilog Porosity shows that both wells encountered essentially the same subsurface geology.

1 . 1 . 1

Top 450 ft. appears to consist of gravel and sand with some clay layers belonging to Santa Fe group of basin fill. Underlying this, rhyolite gravels were encountered between 450 and 750 ft. and again between 850 and the bottom of the wells, with an intermediate layer of gravel and sand of heterogenous composition. It has not been determined as yet whether the rhyolite gravels represent a rhyolite flow, such as an extension of soledad rhyolite encountered in Organ Mountains or a deposit of short distance transported material, such as an alluvial fan or bajada slope deposit. The bottom hole temperature in both wells was approximately 63°C.

Introduction

Las Alturas geothermal area, which lies between highway I-25 and Tortugas Mountain in the Southeastern part of Las Cruces, has been under active investigation since at least 1975 (Gunaji, et.al. 1978; Jiracek and Gerety, 1978; Swanberg, 1975). In November, 1978, the decision was made to drill two exploratory wells, 1000 to 1500 ft. deep, to gather information regarding the subsurface conditions -- stratigraphy, temperature gradient, groundwater, etc. Location of the two wells was determined on the basis of previous work completed, primarily electric resistivity and shallow temperature gradient survey. The wells were drilled about 0.6 mile and 1 mile east respectively from the NMSU solar houses south of NMSU golf course along the dirt road going towards Tortugas Mountain. Location of the two wells is shown on Figure 1.

The two wells, numbered NMSU-DG-1 and NMSU-DG-2 (New Mexico State University - Deep Geothermal Wells 1 and 2) were drilled during December 27, 1978 to January 3, 1979, by Johnson Drilling Company of Las Cruces, using a rotary drilling rig. Well no. 2 is located at 52 ft. higher ground elevation compared to well no. 1 (4163 ft. and 4111 ft. above m.s.1. respectively). The bottom hole temperature in both wells was approximately 63°C.

Fig. 1. Location of wells NMSU-DG-1 and NMSU-DG-2

Geologic Setting

44.00

Figure 2 shows a generalized geologic map of the Las Cruces area, reproduced here from King and Hawley (1975). The area contains Paleozoic, Cretaceous and Tertiary sedimentary and volcanic rocks. Igneous intrusive rocks of Precambrian and Tertiary age make up the cores of the San Andres-Organ Mountain chain, Dona Ana Mountains, Goat Mountain and Picacho Mountain. Surface geologic material near the wells consists of unconsolidated basin fill alluvium of the Santa Fe group. This material mainly consists of sand and gravel of coalescent alluvial-fan surfaces near the surface.

Since much of the unconsolidated material expected in these wells must have been transported from the Organ mountains and Tortugas Mountain area, a knowledge of rock types exposed in these outcrops is essential. Tortugas Mountain is the nearest rock outcrop and rocks exposed there consist primarily of Paleozoic sedimentary rocks-mainly limestone. Thick sequence of silicic volcanics consisting of basal ash-flow tuffs (cueva tuff) and flow-banded rhyolite and ash-flow tuff (Soledad Rhyolite) is exposed in the Organ Mountains (Seager, 1975). The Organ batholith consists of Quartz Monzonite, which is expected to yield fragments of quartz, feldspars, mica, clay minerals, etc.

Geologic Log

Sampling Procedure. Samples were collected at 10 feet interval from both wells. The material coming out of the well was passed through a screen to remove the drilling mud and then collected unwashed in Canvass sample bags. Even though this method resulted in some samples being dried lumps, it gave a better idea of the percentage of fines in each sample. The bags were numbered according to the depth of sample collection and stored for later study.

EXPLANATION

Valley-fill alluvium; late Quaternary; clay to gravel, less than 80 ft thick.

Olivine basalt flows and volcanic cones: Quaternary, generally post date the Santa Fe Group.

Basin-fill surface. Santa Fe Group, with discontinuous overlay (generally less than 25 ft thick) of younger alluvial, colian and minor lacustrine deposits.

Santa Fe Group basin fill: Miocene to middle Pleistocene; clay to gravel; locally as much as 4,000 ft thick. Also discontinuous overlay (generally less than 160 ft thick) of younger valley slope deposits.]sf_

Volcanic rocks, and associated clastic sedimentary rocks, undifferentiated; early and middle Tertiary.

Intrusive rocks, undifferentiated, and associated metamorphics; Precambrian and Tertiary.

Faults involving significant displacements of basin fill.

Fig. 2. Geologic map of Las Cruces area (From King and Hawley, 1975)

Laboratory Procedure. The samples were examined under a binocular microscope at 10x-25x magnification. Most samples were examined first unwashed and then again after washing them. Examination of unwashed samples gave an idea of the presence of fine material other than the drilling mud. Washing the sample made the identification of rock types much easier.

Interpretations. Figures 3 and 5 show a summary of lithologic logs. These summaries were prepared after a detailed examination of 120 samples for well no. 1 and 100 samples for well no. 2. There is a great deal of similarity of lithologic horizons encountered by the two wells. The contacts encountered by NMSU-DG-2 are 20-50 ft. higher than those found by NMSU-DG-1. This is to be expected, since the sediments (and flow?) are derived from the source area to the east and the dip is to the west. The eastern well (DG-2) is also situated 50 ft. higher than DG-1.

There are five major zones identified by lithologic logging. The top layer consists of sand and medium to coarse size gravel apparently derived from a host of rock types viz. granitic intrusive rock, rhyolite flow, ash flow tuff, and others. The water table was encountered at about 265 ft. below the ground surface in both wells. All geophysical well logs clearly indicate this. Lithology below the water table is similar to that found above the water, except that some distinct layers of clay were encountered in sand and gravel. From about 420 ft. down, the rock cuttings indicate a very uniform lithology, with the exception of an approximately 100 ft. thick layer between 770 ft. to 870 ft. in DG-1 and 720 ft. to 850 ft. in DG-2. This layer consists of clearly fluvial subrounded gravel, sand and some clay, of a heterogenous composition. The layers above and below this apparently fluvial zone present a problem which has not yet been completely resolved. The zone between 420 ft. to 720 ft. and 850 ft. to the bottom consists of very uniform,

fine or medium (approximately 1/8" to 1/4") angular to subangular (and occasionally subrounded) fragments of rhyolite or rhyolitic tuff. It would be easy to call these zones as rhyolite flows (perhaps Soledad Rhyolite) except that there are indications to the contrary. Although a majority of fragments sampled from both wells for these zones are angular, there are enough subangular/subrounded fragments to indicate that these fragments are transported some distance. Also, although the drilling through these zones was difficult, it was not difficult enough to consider these as continuous rhyolite flow beds. These zones could possibly represent highly fractured rhyolite flows separated by a 100-150 ft.-thick sedimentary bed or could possibly represent alluvial fan or bajada deposits developed on rhyolitic bedrock. All geophysical logs attest to the uniformity of these zones. The question is left here unresolved with the suggestion that in any future drilling through these zones, core sampling be done through at least parts of these zones and the cores carefully analyzed.

Geophysical Logs

Introduction. Two sets of logs were run in each well soon after drilling was completed. The logs were run by the commercial logging firm-Dresser Atlas. One set, called "Dual Induction Focused Log" contained Spontaneous Potential and three resistivity logs viz. Shallow Focused, Medium Induction and Deep Induction. The second set, called, "Compensated Densilog/Compensated Neutron" contained Caliper, Gamma Ray, Compensated Neutron and Compensated Densilog. Figures 3 and 5 show the interpretations of each of these logs. Figures 7 and 8 show the original logs for wells no. 1 and 2 respectively. Borehole geophysical logs have been successfully used by petroleum, mining and to a lesser extent, groundwater industries for almost half a century or more.

1000		AMOUNIS OF QUARIS, FELDSPARS, EIC.

. .

Log interpretation techniques have, therefore, been perfected for sedimentary strata analysis. Log interpretation of logs run in igneous rocks sequence generally has to rely on known properties of such materials and how these may affect various logging parameters. Not much interpretation literature is available for log interpretation for geothermal parameters identification, i.e. rock permeability, temperature vs. salinity affects on resistivity and spontaneous potential in igneous rock sequence.

Following is a summary of points of special interest concerning each log type.

<u>Resistivity/Spontaneous Potential</u>. Spontaneous potentials are usually produced by interactions between shale, interstitial water in sandstone and drilling fluid. Since there are no classic shale, sandstone, limestone sequence here, SP curve is generally flat and is not of much use.

Resistivity contrasts too are not as pronounced here as would be expected in a classic sedimentary sequence. However, induction and shallow focused resistivity profiles are used here to identify water-bearing gravel beds from essentially dry and uniform rhyolite rock matrix.

<u>Caliper</u>. Caliper log has been used to delineate areas of caving and of rugged rock like section. It has also been used to correctly interpret other logs, since in caved areas, other log responses are seriously affected by the borehole fluids rather than formation properties.

<u>Gamma Ray</u>. Gamma Ray log is a passive log. It counts natural radiation without providing any stimulation. In sedimentary sequence, Gamma Ray log is commonly known as shale log, since Potassium 40 found in shales show a high response. In the two holes presently under discussion, Gamma Ray showed a high value (>200 A.P.I. units) against rhyolite zones. This is to be expected, since rhyolite has abundant potassium feldspar (orthoclase) and potassium mica (Sericite/muscovite), which contain radioactive Potassium 40.

<u>Neutron/Densilog Porosity</u>. These logs are a measure of hydrogen ion concentration in the formation rock. The highest porosity in both the wells is indicated, as would be expected, against water saturated gravel and sand just below the water table. However, fairly high porosity (16-20% in the upper rhyolite layer, 12-16% in the lower rhyolite layer) is indicated against rhyolite layers. This could be due to water trapped within crystals in igneous rocks in minerals such as biotite and hornblende. There must be water in fractures as well. The porosity indicated is, therefore, most likely much higher than the acutal porosity of these zones. Densilog is a variation of Neutron logging. Both provide almost identical values for each strata.

<u>Interpretations</u>. Figures 3 and 5 show a summary of characteristics noted for different zones by each logging device. The acutal logs are shown in Figures 7 and 8.

There is a good correspondence between responses recorded by each logging tool. Thus, dry sand and gravel show relatively high resistivity (approx. 100 ohm-m), uniform and relatively low gamma ray response (80 to 100 A.P.I. units) and low neutron/densilog porosity indicating dry conditions.

Alternating layers of sand/gravel and clay show fluctuating resistivity, caving zones in caliper log, fluctuating gamma ray (high against clay due to presence of potassium 40) and fluctuating porosity log response.

199

Water table is clearly indicated by all logs. Resistivity curves record a sharp decrease after some fluctuations, perhaps due to the presence of capillary water above the actual water table. Highest porosity values are indicated by Neutron and Densilog against the water saturated zones.

Against Rhyolite zones, resistivity values are higher and uniform throughout, gamma ray response is highest (>200 A.P.I. units) and porosity values are 14-20% (probably high, as explained above). Conclusion.

.

The two wells, NMSU-DG-1 and NMSU-DG-2 have encountered Bolson sediments of Santa Fe group to a depth of approximately 450 ft. Below this level, rhyolite rock gravel was encountered which could be a fractured rhyolite flow or an ancient alluvium fan deposit derived from Soledad rhyolite. There is a second layer of gravel and sand between approximately 750 to 850 feet, below which another layer of rhyolite "gravel" was encountered. Ground water table in both wells was encountered at 265 feet below the ground surface.

The ground surface, as well as all the horizons, slope to the west, dropping about 50 feet in 0.4 mile, i.e. a dip of about 1.4° .

ACKNOWLEDGEMENTS

This work was funded by the Department of Energy, Division of Geothermal Energy under Contract no. EW-78-5-07-1717.

14

Help of Dr. N. N. Gunaji during drilling of the wells and arranging for sample collection is gratefully acknowledged.

Discussions with Professors William R. Seager and Robert Robinson of the Earth Science Department (NMSU) helped in clarifying some points regarding local geologic setting.
