

Calculation of Drainage Areas

$P_c = 670$ psia

$T_c = 387$ degrees R are the critical properties of the Feather Morrow gas

$T = 184$ degrees F or 644 degrees R is the bottomhole temperature

$P = 5481$ psia is the original bottom-hole pressure from DST #3 on UTP #1

Then, $P_r = \text{Pressure}/P_c = 5481/670 = 8.18$

$T_r = \text{Temperature}/T_c = 644/387 = 1.66$

The Standing and Katz chart says the Compressibility Factor (z) = 1.02 for this gas.

The formation volume factor is $B_g = 35.35 \cdot P/z \cdot T$

where $P = 5481$ psi

$z = 1.02$

$T = 644$ degrees R

so that $B_g = 35.35 \cdot 5481 / (1.02 \cdot 644)$

$B_g = 295$ Scf per cubic foot

Then, we calculate the drainage area (A) from the volumetric equation

$$G_p = R_f \cdot 43560 \cdot A \cdot H \cdot \Phi_i \cdot (1 - S_w) \cdot B_g$$

where $G_p =$ Gas Produced in Scf

$R_f =$ Recovery Factor (assumed equal to 0.80 for normal rock)

$A =$ Drainage Area in acres

$H =$ Reservoir height in feet

$\Phi_i =$ Reservoir porosity, fraction

$S_w =$ Water Saturation, fraction

$B_g =$ Formation Volume Factor in Scf/cubic foot

Note that $H \cdot \Phi_i \cdot (1 - S_w) = H \cdot \Phi_i \cdot S_g$ is the hydrocarbon pore volume calculated for each of the wells.

Now $G_p = 0.80 \cdot 43560 \cdot A \cdot [H \cdot \Phi_i \cdot S_g] \cdot 295$

$G_p = 5.719 \cdot 10^6 \cdot A \cdot [H \cdot \Phi_i \cdot S_g]$

and $A = 1.748 \cdot 10^{-7} \cdot G_p / [H \cdot \Phi_i \cdot S_g]$

where we already know the equivalent gas produced (G_p) and the hydrocarbon pore volume ($H \cdot \Phi_i \cdot S_g$) for each of the wells.

As an example for the current drainage area of the UTP #1 well,

$$A = 1.748 \cdot 10^{-7} \cdot 1.792 \cdot 10^9 / 1.826$$

$$A = 313.2 / 1.826 = 172 \text{ acres}$$
