RE: Proposed:

Gentlemen:

I have examined the application for the:

-tt-<u>6-165-35e</u> · 025 · 27891 obrating I mern Operator S-T

and my recommendations are as follows:

Yours very truly,

Chris Williams Supervisor, District l

/ed

March 20, 2000 POST OFFICE BOX 1433 ROSWELL, NEW MEXICO 88202 (505) 622-1001 FAX (505) 625-0227

David R. Catanach NMOCD District IV 2040 Pacheco Street Santa Fe, NM 87505

> Re: Application for Downhole Comingling Tilley #1, Unit N, Sec. 16, T16S, R35E Lea County, NM

Dear Mr. Catanach:

Please find the enclosed items pertaining to the subject Application for Downhole Comingling:

Form C-107-AApplication for Downhole Comingling

2 C-102 forms, one for each zone to be downhole commingled

Production curve showing monthly production for the Atoka gas zone while it was produced by itself

Production curve showing daily production for the well as it produces today

This well originally produced from the Devonian formation but was plugged by the previous operator. Primero Operating, Inc. re-entered the well in May of 1998 in order to test the Atoka formation. After the plugs were drilled out and the Atoka formation was perforated from 11,430' to 11,448' and we swabbed the well to test for natural entry of gas from the Atoka formation. While swabbing the well, we started swabbing un-cured cement then oil. A RA-Tracer/Temperature survey was run which indicated that the oil being swabbed was from the Devonian open hole section from 12,508' to 12,558', the original producing zone.

We set a retrievable bridge plug over the Devonian formation and subsequently tested the Atoka formation. Treating pressures on the Atoka formation were very high (> 10,000 psi). Production from the Atoka formation was very disappointing, initially the well produced 100 mcfd and over the next 16 months, production fell to below 10 mcfd. Several attempts to swab the well but it did not help production. The original SIBHP for the Atoka was 4694 psi (.41 psi/ft), after 16 months of production, the SIBHP was 3584 psi (.313 psi/ft).

In January 2000, Primero pulled the production packer and retrievable bridge plug from the well and ran a packer, tubing and rods in order to rod pump the well. The seating nipple is set at 9314', above both the Atoka perforations and the Devonian open hole. We did not know if the Devonian production would stay at a commercial rate or if it would water out as it did originally, and by pumping from a higher position in the well we figured that we had less chance of watering out the zone and also kept the costs lower by being able to use a smaller pumping unit and less tubing and rods. Since we did not know how long the Devonian production would last or if it even last more than a few days, we did not squeeze off the Atoka perforations. It is also possible that by keeping the fluid pumped off the Atoka, that it may give up some gas. According to the Roswell Geological Society Oil and Gas Field Symposium, the original SIBHP in the East Shoebar Devonian field was 5017 psi. Based on static fluid readings, the current SIBHP for the Devonian formation is 4377 psi (.349 psi/ft).

Luckily, the well seems to be holding steady and it appears that it will have a long life. I submitted the appropriate paperwork to the NMOCD in Hobbs but they said that I need to apply for downhole comingling since the Atoka perforations are still open.

Copy For NMOCD - Hobbs

Since we are not able to get a production rate for the Devonian formation only the production shown in the "Lower Zone" section of the Application for Downhole Comingling form is the total the total current production from both zones. For the "Fixed Percentage Allocation Formula", I used the last full monthly production from the Atoka by itself, September 1999 (14.2 mcfd) and assumed that this is the gas production from the Atoka formation. I divided the 14.2 mcfd from the Atoka into the total current gas production (19.34 mcfd) to get a factor of 73% of the gas allocated to the Atoka Formation leaving 27% of the total gas to the Devonian formation.

We hereby request administrative approval to downhole commingle production in this well based on the following:

- (i) Commingling is necessary in order to allow the recovery of gas reserves from a marginally producing formation (Atoka)
- (ii) The bottom-hole pressure of the highest pressured commingled zone does not exceed the original reservoir pressure of any other commingled zone in the wellbore adjusted to a common datum.
 (Current Devonian pressure gradient is .349 psi/ft while the original Atoka formation gradient was .41 psi/ft)
- (iii) The commingling will not result in the permanent loss of reserves due to cross flow in the wellbore (Based on bottom hole pressures for both the Atoka and Devonian formations and the extremely high pump in pressure required for the Atoka formation, cross flow will not occur)
- (iv) That based on the high pump in pressures witnessed on the Atoka formation, fluids from the Devonian formation will not be able to enter the Atoka and cause any more damage than may already be present.
- (v) The fluids from the two zones are compatible and comingling the fluids will not result in the formation of precipitates which might damage any of the reservoirs. (As evidenced by the steady production trends witnessed since the well was put on pump)

The ownership of the two zones is the same and all owners are anxious to see the well produce in the most economic fashion. If you have any questions regarding this request, please do not hesitate to call me.

Thank you,

Phelps White President
