- 14. GIH with 3 3/4" bit, drill collars, and 2 3/8" tubing and clean out to TD 6565', checking for fill in the open hole section 6476'-6565'. POH.
- 15. Dependent on logs, rig up wireline unit and selectively perforate additional Drinkard pay from  $\pm$  6350-6476', actual perfs will be taken off GR/Compensated Neutron log. Perfs will be 2 spf with a 4" casing gun.
- 16. POH with perforating gun.
- 17. GIH with treating packer and 2 3/8" tubing.
- 18. Spot 500 gals. 15% NEFE acid across open hole and perforated intervals.
- 19. Pull packer to <u>+</u> 6200'. Displace 10 bbls of water down back side and out tubing to insure no acid is left above packer.
- 20. Set packer at + 6200'.
- 21. Frac Drinkard open hole interval, (See note), and additional perforations, if any, with 36,000 gals. gelled water with 48,000# of 20/40 sand in 3 stages. (Will use Dresser Titan's stimulation recommendations).
- 22. Flush with gelled fluid. (Not crosslinked)
- 23. Begin return of load.
- 24. Test and evaluate the Drinkard interval for 30 days.
- 25. If Drinkard is not commercially successful, evaluate recompletion possibilities in Paddock, Tubb, & Blinebry intervals.
  - Note: If sufficient room is present between upper Drinkard perfs and the open hole, the packer will be set below the perfs and the open hole will be separately fraced. Then the packer will be raised above the perfs, block will be pumped into the open hole and the perfs will be fraced separately.
